patient himself, it is sought to beneficially influence the disordered functions of the body. In the words of Dr. T. CLAYE SHAW, who opened the discussion at the Harveian Society, psycho-therapeutics postulates "the existence of conative processes, such as Will, Faith, Power of Attention, treating these as actual entities which can be influenced by being strengthened when weak or called into energy when dormant." It is, we venture to think, one of the most extraordinary paradoxes of our time that though the modern school of psychology is, as Dr. SHAW points out, usually materialistic in its teaching, insisting that will, attention, and conative processes are results not causes, and that there are no such things as primitive faculties in the direction of compelling forces, yet that the latest remedial measures put forward as of extreme validity involve an appeal to that very will and attention whose existence, in the laboratory, is strenuously denied. Monistic materialism may be our creed, but if so, it is a creed which must be disregarded in practice. We publish this week an interesting article by Dr. CHARLES MERCIER, written with characteristic directness from a more metaphysical point of view than we are accustomed to find in a medical psychologist. We commend the perusal of this short article to our readers. Dr. MERCIER points to the impossibility of picturing the neurons of the brain as containing or producing a sound of high C or an emotion of anger. These mental states are not in the brain, they are in the mind. "There is no community of nature between the vibrations of molecules in the neurons of the brain and the thoughts, passions; and volitions that occupy the mind. There is utter separation: between the mental and the material there is a gulf that no imagination can bridge." We recall that Dr. MERCIER, in his presidential address at the annual meeting of the Medico-Psychological Association last year, laid stress upon the importance of preserving the inescapable responsibility of each individual for his acts. It is to that sense of responsibility that whoever practises psycho-therapy, whether consciously or not, makes appeal; and where the physician finds it absent the feebleness of his remedial measures is most apparent.

Annotations.

"Ne quid nimis."

THE LANCET REPORT ON THE STANDARDISATION OF DISINFECTANTS.

WE have pleasure in submitting to our readers this week the first part of a report by a Special Commission of Inquiry, appointed by us, upon the Standardisation of Disinfectants. For some years past we have had abundant evidence before us that the whole question was in an unsatisfactory position. It has received careful and independent attention at the hands of several scientific observers who set themselves the task of determining whether any method could be trusted to represent the actual germ-killing capacity of a given disinfectant. No recognised method appears to have received an absolute consensus of opinion in its favour. Either there was something wrong in regard to the conditions under which the experiments were made or the deductions were

¹ See Thin Labour, Nov. 8th, 1969, p. 1369.

fallacious. Methods both of bacteriological and chemical analysis were freely discredited, and the situation was not helped by the personal feeling imported into scientific disputes. The position was clearly a case for an independent tribunal, and as the question was one of the first importance from a sanitary point of view we decided that it was also a very proper one for THE LANCET to investigate. The first part of our report is published this week and deals with the chemical side of the question. It is suggested that in the light of these results the chemical analysis of disinfectants, when based upon accurate methods, promises to assume an importance which hitherto has not been recognised. This view will be found to be strengthened when the facts brought to light in these analyses are taken into account with the results of bacteriological examination, which forms the second section of the report.

THE BIRTHDAY HONOURS.

THE most distinguished name amongst the few scientific men who have received recognition in the recent distribution of Birthday Honours is that of Sir Henry Enfield Roscoe, F.R.S., Emeritus Professor of Chemistry, Owens College, Victoria University, and late Vice-Chancellor of the University of London, who has been given a seat in His Majesty's Privy Council, a distinction which Huxley always maintained was the proper award for high scientific service to the country. There are only three medical men in the list. Among the new Knights is the name of Mr. James Matthew Moody, L.R.O.P. Edin., M.R.C.S. Eng., who has been the medical superintendent of Cane Hill Asylum for a quarter of a century and was at one time senior assistant medical officer at the Brookwood Asylum, Woking. The award is a proper, if tardy, recognition of the great value of the work done by asylum medical officers. Mr. George Herbert Pollard, M.P., M.D., C.M. Edin., who also receives a knighthood, is a barrister-at-law of the Inner Temple, and has been a Member of the Eccles Division of Lancashire since 1906. In 1897 he was elected to the mayoral chair of the borough of Southport, of which place he is a Justice of the Peace. In the Colonial list is the name of Mr. James Augustine Haran, M.D. Dub., medical officer of health at Mombasa in the East Africa Protectorate, who has been made a Companion of the Most Distinguished Order of St. Michael and St. George. Miss Annie Fletcher has received the decoration of the Royal Red Cross in recognition of devoted service rendered by her to Their Majesties the King and Queen since 1902. Although not a member of the medical profession, the Right Hon. Sir Savile Crossley, Bart., M.V.O., who has been made a Knight Commander of the Royal Victorian Order, has been indefatigable in his work for hospitals, especially in connexion with the King's Fund, the Metropolitan Hospital Sunday Fund, and the Hospital Saturday Fund. We heartily congratulate him upon his well-deserved honour. Mr. Somerville Arthur Gurney, who has been made a Knight Commander of the Victorian Order, is treasurer of the West Norfolk and Lynn Hospital, and was informed of his approaching honour when the King visited Lynn last week to inspect an art loan exhibition, of which Mr. Gurney was chairman, in aid of that hospital. Professor William Augustus Tilden, D.Sc., F.R.S., who has also been knighted, is at present Dean of, and Lecturer of Chemistry in, the Royal College of Science, London, and has held the highest official positions in the profession to which he has devoted his distinguished attainments. Amongst the most popular of the new honours will certainly be those awarded to Sir Ernest H. Shackleton and Dr. Sven Hedin, K.C.I.E., both of whom have shown such physical endurance and indomitable pluck in their respective fields of exploration.

THE DEVELOPMENT OF THE CORSET.

Mr. Arbuthnot Lane, in a paper which appears on another column, draws attention to one disadvantage of civilisation affecting most of us in the present day. He points out that owing to our habit of either standing or sitting on chairs for 16 hours out of the 24 the trunk is kept erect, and therefore there is a tendency for the viscera to drop. Nature, he says, endeavours to overcome this tendency by the formation of peritoneal bands which help to hold up the viscera, but these acquired bands in their turn may set up kinks in the hollow viscera and so bring about disaster. Hence, he is led to advocate the use of a well-fitting corset—i.e., one which will exercise a firm pressure in a backward and upward direction on the abdomen below the umbilicus. and will leave the upper part of the abdomen free. The English corset as at present manufactured he regards as harmful, but the straight-busked French shape is, he says, much less harmful, and "if skilfully made and applied serves to exert a moderate pressure on the lower abdomen." We fear that some very radical change will have to be made in the dress of women before they will consent to wear a corset merely for reasons connected with health. At present the corset is worn for two main reasons—firstly, to afford a firm basis for the support of the skirts; and secondly, to accentuate, or to manufacture, certain characteristics of the female body, commonly termed "the figure." The development of the corset, so far as its evolution can be traced, is an interesting subject. Until recently it was probable that the women of the early civilisations did not wear anything to compress that part of their bodies which lies between the last ribs and the crest of the ilia. But various objects discovered in Crete by Mr. Arthur Evans and his fellow workers show that the people of that island in very early times were, at all events, represented in pictures and on seals as having waists compressed to an abnormal extent. The date of these pictures is placed at 4000-3000 B.C., and reproductions of some of them have been exhibited at Burlington House. One of them is reproduced in Miss Jane Harrison's Prolegomena to the Study of Greek Religion, showing the Mountain Mother and her Mystes, both with waists rather smaller than their necks. Coming to the Greeks of more historical times, we find mention in Aristophanes of a device called strophion, a strip of linen very similar to the modern bust-bodice, and like ft used for the purpose of elevating and supporting the breasts. It was also called "mammillare" by the Romans, and in the case of very large mammary development it was made of leather, as appears from an epigram of Martial. In somewhat earlier times we find the fashionable ladies of Rome severely dealt with by Terence (ob. B.C. 159). In his play Eunuchus, ii., 3, 21, he says:

Haud similis virgo est virginum nostrarum quas matres student Demissis humeris esse, vincto pectore, ut graciis sient. Si qua est habitior paullo, pugliem esse alunt, deducunt cibam. Tametsi bona'st natura, reddunt curatura junceas."

The girl is not like our girls who their mothers are anxious should have narrow sloping shoulders and their chests tightly bound up, that they may be slender. If any one of them is rather more fleshy them usual they say she looks like a prizefighter and cut down her food. Notwithstanding that Nature is good enough, they make them by careful attention as slim as a rush.

Everyone knows how young girls were disciplined in the eighteenth century with backboards and tight stays, but from the above quotation it is evident that the Roman girl was none the more exempt from the tyranny of fashion. It is easy to see how the simple strophion gradually grew larger and stiffer until it culminated in the formidable stays and stomachers of Blisabethan times, and the corset remained much the same down to the early years of the nineteenth century. More sensible views now prevail, and few women compress themselves as their mothers and

For this relief credit is due to the development of exercise among women and to the use of the bicycle and the motor-car. But, as Mr. Lane points out, the use of a corset constructed to aid instead of to weaken the

abdominal muscles is a matter which concerns the medical profession in a marked degree, and it may be that in time the influence of medical men who study the matter will enable fashion to go hand in hand with good sense.

THE FATE OF THE LONG-HEADED BLOND RACE.

THE Royal Anthropological Institute of Great Britain and Ireland was particularly happy in its choice of Professor Gustav Retzius of Stockholm as Huxley lecturer for the current year. He is a son of Anders Retzius, who in 1840 divided mankind according to the shape of their heads into Gentes Dolichocophalæ and Gentes Brachycephalæ, and thereby laid the foundation on which the great superstructure of modern craniology has been reared. In delivering the Huxley lecture at the new premises of the Institute in Great Russellstreet, Professor Retzius dealt with the increase of knowledge regarding the origin and distribution of European races which had attended the application of the methods introduced by his father. A recent survey of recruits for the Swedish Army revealed the fact that 87 per cent. of the Swedes are "long-headed," while 73 per cent. have fair hair. Professor Retzius regards his fellow countrymen as a pure representation of the North European race-a race still found in Scandinavia, North Germany, and Britain, but at one time spread widely over Europe-from earliest neolithic times downwards. They may be regarded as the aborigines of Europe, not, as at one time widely believed, Aryan invaders from Asia. Professor Retzius agrees with those who take a gloomy view as to the future of this ancient race. The qualities which made them great in the past are just those that unfit them for the routine life of an industrial civilisation. The round-headed darkhaired race which has replaced them in central Europe has gained its victory by the possession of superior industrial qualities, a superiority that threatens ultimately to overwhelm the fair-haired North European stock. Professor Retzius is not one of those who believe that an industrial mode of life can alter the shape of the head or colour of the hair; the evidence in support of such a hypothesis is altogether unconvincing. Such questions, of the very greatest importance to industrial nations, can be settled only by a comprehensive physical survey of the people.

AN INTERNATIONAL CONGRESS OF RADIOLOGY AND ELECTRICITY.

WE are informed that arrangements have been made for an International Congress of Radiology and Electricity to take place at Brussels in connexion with the exhibition to be held there in 1910. The Congress, which will meet on Sept. 6th, 7th, and 8th, will be held in three sections. In the first section, general questions of terminology and methods of measurement in radio-activity and subjects connected with ions, electrons, and corpuscles will be dealt with. The second section will be divided into various subsections, dealing respectively with fundamental theories of electricity, the study of radiations (including spectroscopy, chemical effects of radiations, and other allied questions), radio-activity, atomic theory, cosmical phenomena (including atmospheric electricity and atmospheric radio-activity). The third section will be biological and will be devoted to consideration of the effects of radiations on living organisms. The section will deal with purely biological questions as well as with the use of various radiations for medical pur-

ensure the success of the Congress committees have been formed in the various countries which will take part in the Congress, and the following scientists have already consented to act as presidents of the committee in each country: Professor Lenard (Germany), Professor Exner (Austria), Professor Oëtvös (Hungary), Professor Castillo (Spain), Professor Barus (United States), Professor Langevin (France), Professor Rutherford (Great Britain), Professor Blaserna (Italy), Professor Birkeland (Norway), Professor Lorentz (Holland), Professor Ferreira da Silva (Portugal), Professor Hurmuzescu (Roumania), Professor Lebedew (Russia), Professor Arrhenius (Sweden), and Professor Guye (Switzer-Communications regarding the Congress may be addressed to Professor Rutherford or Dr. W. Makower at the University of Manchester, but anyone wishing to become a member of the Congress should communicate his intention directly to the general secretary, Dr. J. Daniel, 1, Rue de la Prévôte, Brussels. Communications relating to the Biological and Medical Section should be addressed to Mr. W. Deane Butcher, Holyrood, Ealing, London, W,

ILLUSTRATIONS IN A NEWSPAPER.

In another column will be found an account of an interesting case of fracture of both patelles by direct violence in a patient under the care of Mr. William Sheen. The first illustration to this article is of a more frivolous nature than generally characterises our pictures, but we have admitted it for the very good reason that it gives at a glance the exact method, a rather complicated one, in which the injury was brought about. The original sketch was not, of course, intended for reproduction in the columns of a scientific journal. In providing illustrations for articles for the scientific press it must be remembered that the object of the author should be not, in the first case, to produce an artistic result so much as to give a picture which will show exactly what the writer means to express. It is quite possible to combine extreme technical accuracy with perfect artistic feeling-a good example of this is Turner's drawing of a windmill given in Vol. IV. of "Modern Painters," in contrast with another drawing of the same subject by Stanfield -but for artists of a meaner kind it is generally necessary to subordinate artistic finish to accuracy of detail or even to make the illustration semi-diagrammatic, especially in pictures dealing with anatomical or surgical subjects. We have been led to make these remarks both on account of the clever sketch accompanying Mr. Sheen's paper and also because of a series of articles now running in our contemporary the Author, written by Mr. W. B. Plummer, on "The Art of Illustrating." Many of our contributors from time to time have thought us captious with regard to the photographs, drawings, charts, and diagrams with which they have supplied us for the purpose of illustrating their articles, because they have not been familiar with the processes of reproduction. Everybody cannot know everything, and the technicalities of illustration for the press may not concern medical men very closely. But the tendency of medical men being more and more towards illustrating their articles, we recommend to those who are interested the study of Mr. Plummer's instructions. In these the mysteries of the line block, the advantages and disadvantages of the wash drawing, and the necessity of using certain materials are all explained in a very clear manner. We may briefly refer to two little matters which have frequently prevented us from reproducing a drawing or a chart exactly in the form in which it has reached as. A. chart may be drawn so that the curve will reduce to a third. or even less of the original size without losing clearness, but only if the figures or the letters written upon at have been posses, both for diagnosis and therapeutics. In order to drawn on a scale to allow of the reduction. As a rule, the lettering of charts is so small that on reduction the details become illegible. The other matter is a question of colour. Many charts are sent to us drawn on squared paper printed in blue. As the blue does not photograph at all the curve is practically useless, as it appears on a perfectly blank background. Again, in a chart dealing with say, pulse, respiration, and temperature, some contributors send them in drawn in black, red, and blue. A chart drawn thus, if photographed, shows only two black curves corresponding to the red and the black, while the original blue curve does not show at all. Therefore, unless it is intended to have the chart printed in colours, the difference in the curves should be indicated by dotted or broken lines. These few explanations will show the reason why certain drawings cannot be published, and will also, we hope, enable those who wish for the publication of drawings or charts to avoid technical errors which cause both trouble and delay.

THE HEALTH OF THE NAVY IN 1908: AN INVESTIGATION INTO THE CAUSES OF HEAT-STROKE.

FROM the report on the health of the navy in 1908 it is satisfactory to find that there is a continuous improvement, the figures for 1908 showing lower ratios of sickness, invaliding, and mortality than in the preceding five years. It is regrettable, however, to find that venereal affections show no diminution, in contrast with the considerable decrease that has occurred in this class of disease in the army during the last few years. On the other hand, the saving of inefficiency and suffering in the reduction of Malta fever in the Mediterranean command has been most satisfactory: the admission-rate was 0.61 per 1000, whereas in the preceding five years it had been 14.67 per 1000; the disease has been practically extinguished in the navy as well as the army in Malta. The appendix contains an interesting report by Staff-Surgeon Oswald Rees, "Body Temperature and the Causation of Heat Stroke," with detailed observations of physiological conditions as found in the stokehold and engine-room of a cruiser in the Red Sea during September. We regret that this should be the only contribution of original research, and, indeed, the only matter in the whole volume that is not purely statistical. The report itself, as distinct from the tabular material, is hardly anything but a résumé of the figures; it cannot be described as their essence, but rather as an extractum exsicoatissimum, devoid of any savour or aroma of interest. As we remarked on the occasion of the similar report for 1907, it seems to us a pity that so much labour should be expended in the compiling of returns and official reports without any practical lesson being deduced from them by the experts best qualified to judge of their significance. In Staff-Surgeon Rees's report reference is first made to Dr. J. S. Haldane's researches on "critical" temperatures, and an account is given of the author's experiences during the passage of H.M.S. Fox through the Red Sea on her way to the East Indies station in the month of September. Staff-Surgeon Roes and Surgeon G. A. S. Hamilton for a certain period spent the first dog-watch of each day (i.e., 4 P.M. to 6 P.M.) either in the stokehold or engine-room. It was found to be impossible to carry out observations on the stokers, therefore the medical officers experimented on themselves. They imitated the actual work of the stokers-which is very severe while it lasts, but intermittent, and carried on in a brisk current of air (150 to 600 linear feet per minute), but exposed to intense heat and glare—by climbing up and down a ladder in front of the furnaces. Under the conditions of the experiment it appeared that 83° to 84° F. was the "critical" wet bulb temperature for both observers, when

working in the stokehold of this vessel, steaming at about 10 knots. This critical temperature must vary in each ship under varying local conditions, such as rate of steaming, position and kind of furnace, use of forced draught, &c.; and probably also varies with the individual, the seasoned stoker's critical temperature being higher than that of the unseasoned man. No stoker needed treatment for heat-stroke until the wetbulb temperature averaged 87° F. On Sept. 8th this was found to be the temperature of the stokeholds in use, whilst in the engine-room it varied from 87° to 96°, so that in both departments the conditions were critical and cases of heatstroke were to be expected. Even on deck the wet bulb reached 85° from 4 P.M. to midnight, the dry bulb registering 91°. 13 cases of heatstroke occurred, with 1 death. Of the three most severe cases, one (a ward-room servant) had fallen asleep with his head exposed to the full blaze of the sun; the second was a cook who had been exposed to the heat of a galley fire; the third was an engineroom artificer, exposed to the engine-room temperature, complicated by a heavy meal of "butter beans" which he had bolted. "Of the other cases the determining cause seems to have been 'fright' pure and simple, as there was a perfect panic among the young stokers." The following practical conclusions are drawn: the necessity for (1) careful observations on wet and dry bulb temperatures in engine-room and stokehold in the tropics; (2) the provision of ventilating fans in engine-room; (3) the taking of external wet and dry bulb observations so that when the former reaches 80° F. all the crew may sleep on the upper deck or in a free-air current; (4) instruction as to causation of heat-stroke so that over-eating, and so on, may be avoided; and (5) energetic treatment of heat-stroke itself by iced bath combined with cold lavation of the bowel. Staff-Surgeon Rees thinks that possibly the amount of meat in the sailor's dietary may be reduced and carbohydrates substituted as soon as the wet-bulb temperature reaches 80° F.

THE REQUIREMENTS AND THE REGULATION OF SIGNALLING BY COLOUR.

An article with the above heading appears in the American Journal of Ophthalmology for October, 1909, from the pen of Dr. Charles Oliver of Philadelphia, who has devoted much attention to the subject. In this the author dwells on the importance of normal perception of colour in situations where accurate colour vision is one of the main requisites, or is the sole determining factor for the safety of lives and for the protection of property. The author points out that rules for the selection of colour material, for the construction of test objects, and for the choice of standards of necessary colour sense should all be placed under the "supervision of a controlling body, from whom all requisite laws must proceed." It is surprising that, considering the magnitude of the interests involved and the importance of safety in travelling to a very large section of the population, some State supervision has not been established, but that it has been left to private enterprise to carry out, in many cases imperfectly or at least inadequately, the testing of the normal sense of colour perception in those who are entrusted with the lives of others, though it is known that defects in this very direction are not infrequent. It is to be remembered that the movements even of the mighty vessels that constitute the strength of the navy are guided at night by the same appreciation of the colour of lights displayed as the most unimportant coasting steamer. In addition, specific lights are employed in army signalling and, Dr. Oliver informs us, in geodetic survey work. For ready recognition of colour perception many plans have been suggested. First, direct comparison of pigment colours popularised by Holmgren's wool

test. Secondly, direct comparison of spectral colours, a plan that is satisfactory, but which requires a somewhat complicated apparatus. Lastly, the study of subjective simultaneous colour and after-colour (complementary colour), which Dr. Oliver regards as practically useless. ordinary clinical purposes he considers the selection of wools is the best and readiest method of testing the colour sense, though it cannot be regarded as quite reliable. For signalling on railways and at sea another plan should be adopted, and the testing should be done under the actual conditions which exist whilst the candidate's colour sense is officially protecting life and property. The apparatus he himself employs for the testing of sight among railway employees consists in a fixed framework which can be placed anywhere upon a company's property. Wooden frames containing properly and proportionately sized matchand confusion-colours of bunting for daylight work, or illuminated plates and lanterns of similarly tinted transmitted colour for bad weather or for night time are arranged in a row in any order. A series of five test colours form an upper row, and the comparison colours are disposed in a lower tier. One eye is tested at a time. The examinee then successively designates the nearest numerical match to each of the upper test colours by the actual position of the corresponding colour in the lower tier. The examiner, after obtaining the true colour names of the numbers chosen from an assistant, places the selections on suitable blanks for expert decision and permanent registry. Dr. Oliver thinks the colour signals should be standardised, certified as correct, issued under proper authority, and accompanied by plain and simple instructions for their use. Many points have to be attended to in properly testing for colour vision; thus, for example, to give a green signal light a similar degree of brightness, and therefore the same relative distinctness as red, it must be either five times more powerfully illuminated than the red or be given five times more exposed superficial area. It is marvellous, considering the number of trains that ply daily, not that accidents traceable to defective colour vision occasionally happen, but that they are not of daily occur-Consider that the distance signal is perhaps, in rounding a curve, only visible for a few seconds, that the information it gives has to be acted on instantaneously, and that the particular signal has to be discriminated, as in the neighbourhood of all large centres where many lines meet, from perhaps 50 others; whilst to the look-out man at sea there is the additional source of doubt and hesitation in the fallacious aspect of even the most saturated colours caught through fog or haze, or intermittently seen on the crest of waves.

THE WET OCTOBER.

THE month of October is on the average the wettest of the 12 over the greater part of these islands, but it is very seldom that its rain-yielding capacity equals that of last month in the south and south-east of England. In nearly all parts of the country the number of days on which rain fell exceeded the normal, and it is extremely rare that even wet October affords so many instances of the gauges yielding an inch or more as the result of one day's rain. Early in the month the heavy downpours were mostly confined to Ireland, Scotland, Wales, and the west and north-west of England; these were, however, subsequently eclipsed by the deluge in the southern and south-eastern counties. It is very noteworthy that these excessive rains occurred over a relatively small patch of country, the districts suffering the most being Hampshire, Sussex, and Kent. There were also some heavy falls in Essex and Suffolk, but the north and north east of England had very little or no rain during | but when attempts are made to induce, or even to compel,

the time and the Midlands very little. At Scarborough and Harrogate the month's rainfall was less than usual. The actual amount of flooding naturally varied much in the different localities. Inundations do not. of course, depend entirely on the amount of water falling during a given time, but they depend to a very considerable extent on the topography of the district, the nature of the soil and subsoil, and the capacity of the drains. They also depend to some extent on the quantity of rain that has fallen during the two or three weeks immediately preceding the culminating fall. A relatively dry soil can easily absorb an inch or two of rain that will cause devastating floods if the soil has been soaked almost daily with more than can flow off or percolate to the lower strata. This was exactly the condition in the south and south-east of England last month. The chief feature with the sunshine was its uniform distribution. London had 7 hours more than the average, but its figure of 76 hours was the least, and no less than 43 hours lower than the total at Torquay. During the first three weeks the temperature was above the average, especially at night, but when the wind shifted to the east and north towards the end of the period the thermometer indicated readings many degrees below the normal figure.

THE ASSOCIATION OF HEAD MISTRESSES AND MEDICAL CARE IN SECONDARY SCHOOLS.

WE have received from the secretary of the Association of Head Mistresses a copy of some resolutions carried at the annual meeting held in June last. The first resolution expresses disapproval of external examinations for girls under the age of 16 years. We gather that the idea underlying this resolution is that the excessive preparatory study for the examinations of extraneous bodies is likely to do harm to the younger girls, and there are certainly grounds for this contention. In the internal work of schools, both primary and secondary, care can be taken to adjust the time and subjects of study to the individual capacities of the children,

[†] A day with at least 0 01 inch.

В

ż

2

children to enter for outside examinations the courses of study must be arranged directly for this purpose, and if any child is entered for such an examination individual peculiarities and needs must be neglected in order to fit the child to the Procrustean bed of examination. The second resolution is even of more importance, for it expresses the opinion that there is need for the medical inspection of all children entering public secondary schools, and that provision should be made for re-inspection from time to time. We endorse cordially this expression of opinion. No small proportion of the children who enter for the higher studies, if we may dignify secondary education by this phrase, are unfitted physically and sometimes even mentally for them. The hours in the secondary schools are necessarily longer than in the primary, the work is harder, and though the children are in a sense picked the strain is greater, and therefore it is essential that care should be taken to see that the back is fit for the burden, even though it appears to be considered unnecessary to fit the burden to the back. With the present general idea that book-learning and examinations are the beall and end-all of a child's education, a precaution such as that suggested by the resolution is very necessary. The failures which occur in the lives, both mental and physical, of the children in secondary schools are more numerous than might be expected, though the percentage is certainly small, but most of the failures, be they few or many, could have been avoided by careful medical examination made at the commencement of study and repeated from time to time in the course of school life. Adequate precautions are not taken at present. It is insisted, no doubt, that a child should have no obvious ringworm or other infectious condition with which the child might infect others, but little care is taken that the child shall not receive damage from the study that is intended to benefit, and we are glad to see that the conference of head mistresses recognises this point of view.

OSTEITIS DEFORMANS AND ITS PATHOGENY.

It was in the Transactions of the Royal Medical and Chirurgical Society for 1877 that Sir James Paget first described that "form of chronic inflammation of bones" which bears his name, and since then perhaps a hundred cases or so have been recorded. While the disease therefore is relatively uncommon, and yet easily recognisable, it is somewhat curious that our ignorance of its causation is as great to-day as when the famous English surgeon first drew attention to it. Its occurrence on the Continent certainly appears to be more frequent than in Great Britain, if we are to judge by the literature, but in spite of many carefully examined cases, with pathological reports and, most recent of all, investigation by the X rays, opinion is still much divided on the exact nature of the condition. The old view which regarded it as a late manifestation of congenital syphilis, a form of syphilis hereditaria tarda, is now discredited, a result, in part at least, achieved by radiography, and the same may be said of that other view, according to which Paget's disease is nothing else than chronic rheumatism. Another theory has for a time held sway and still finds adherents-viz., that which attributes the changes to trophic disturbances under the influence of the nervous system. We know that in poliomyelitis, infantile cerebral hemiplegia, tabes, and syringomyeliato mention but one or two-bony changes, often advanced, may be met with, and in a number of instances of Paget's disease diffuse alterations have been found in the spinal cord. But they have never been sufficiently definite or frequent to bring a causal connexion between them and the bony changes within the realm of

probability. During the year two fresh cases have been reported in the pages of the Nouvelle Iconegraphie de la Salpêtrière, one by M. Klippel and M. Pierre Weil, and the other by M. Pascarolo and M. Bertolotti. The first of these concerned a woman, aged 56 years, in whom the disease had made its appearance 11 years previously and had slowly pregressed, without pain. In her the characteristic features of marked overgrowth and thickening of the bones, which curving of the long bones (and scoliosis of the vertebral column) were almost entirely confined to the right side of the body. The curious symptom of an increased surface temperature on the affected side, the difference between the two sides being no less than 5°C., was noted in her case: this symptom has been described by one or two previous observers. There was no discolouration of the skin or evidence of local infiammation. The second case was that of a man, aged 53 years, with a history of 15 years' duration. Here the condition was more or less symmetrical and much more widespread, involving as is usual the bones of the cranium, thorax, and pelvis, and, of course, the long bones. The interesting feature of these two new observations is that the patients were suffering from obvious circulatory disturbances; the man was an arterio-sclerotic, and the woman had mitral insufficiency and was slightly arteriosclerotic. In a large proportion of cases of Paget's disease arterio-sclerosis has been observed, and the view that the condition is somehow a result of vascular changes in the nutrient arteries of the bones has much to recommend it. There must, however, be another element in the causation of the disease which has hitherto escaped the eye of research: arterio-sclerosis is very common; Paget's disease is a rarity.

PUBLICATIONS ISSUED BY THE HUNGARIAN GOVERNMENT FOR THE MEMBERS OF THE RECENT INTERNATIONAL MEDICAL CONGRESS.

THE Hungarian Ministry of Public Worship and Public Instruction has sent us various publications, written in French, that were issued for the special benefit of the members of the Sixteenth International Congress of Medicine which met at Budapest last August. The most remarkable of these is an elaborately illustrated history of the Faculties of Medicine of the Royal Universities of Budapest and of Kolossvár. During the last few years many alterations and improvements have been effected at these universities. The number of chairs, clinics, and professors has been considerably increased. The history of these faculties is traced back to the fourteenth century, and brief allusion is made to the wars and invasions that interrupted the university teaching. Since the recognition of Hungarian autonomy in 1867 there has been, it is claimed, no further interruption to the forward march. The large volume before us, consisting of close upon 400 pages, with plans and photographic reproductions, shows that a great deal has been accomplished. Reproduced from photographs, very graphic illustrations enable us to see the exterior and interior of the various faculties, the institutes of anatomy, physiology, and bacteriology, the theatres, the operating room, the hospital clinics and offices, and the school laboratories-Emulating the example of his colleague of the Ministry of Public Instruction, the Minister of the Interior published two volumes. The first contains a brief description of all the charitable institutions of Hungary. In the opening passages complaint is made that but little has been contributed by private charity, so that what is done is for the most part done by the State. Nevertheless, at the end of the volume we are told that within the last 15 years the number of beds available for charitable purposes in the hospitals has augmented three-fold. In 1898 a law was

promulgated establishing the right to gratuitous medical aid. This necessitated a great increase in the number of hospitals, and the subventions to the hospitals paid by the Ministry of the Interior, which amounted to 2,179,024 crowns in 1898, rose to 5,551,213 in 1908. But, apart from this and in view of the new law, there was created in 1899 a National Fund for the relief of the sick. This fund was constituted by the levying of a direct tax that might be compared to our poor-rates. This tax yielded the first year 2,389,035 crowns and this has increased yearly, so that in 1908 no less than 7,330,400 crowns were raised by direct taxation for the relief of the sick. Added to the subvention from the Ministry of the Interior, this makes a total outlay of 12,881,614 crowns, or £536,725. other volume published by the Ministry of the Interior is devoted to public hygiene in Hungary. First an account is given of the authorities dealing with public health questions and how they are centralised, the chief being, of course, the Minister of the Interior, who has to report annually to both Houses of Parliament on the hygienic condition of the kingdom. The Minister is advised not only by the heads of the various departments but also by a superior council of public hygiene, and we are given a description as to how this council is constituted. Then the authorities for the 63 comitate or counties and the 25 boroughs of Hungary are described. More than 300 pages are devoted to the various details and functions of sanitary administration. These involve the entire legislation of Hungary on sanitary questions. To deal with this would need, not merely an extensive analysis of these laws and a comparison with those of other countries, but also investigations on the spot, so as to see how far they are effectively applied. Laws by themselves are scarcely worth more than the paper on which they are written; the whole point is the effect they have had on the community. But we have here the basis of investigations on public health questions. Whatever the subject of inquiry, the books issued by the Ministry of the Interior explain what is the law on the subject and what particular class of functionaries have charge of such matters. Thus has the Hungarian Government shown its readiness to afford information, and it is very unfortunate that comparatively little use has been made of the facilities thus given. Many, indeed almost all, of the members of the recent Congress hurried away as soon as the sittings terminated. On the other hand, while the Congress lasted there was not a moment but was fully occupied, and it is doubtful whether the books so freely distributed were read before the members reached their homes. But in any case these books should serve as a sort of invitation to revisit Hungary, and at the present juncture of our own Poor-law affairs an energetic statesman might do worse than go there now.

HONOURS IN CONNEXION WITH THE RECENT INTERNATIONAL CONGRESS OF MEDICINE.

THE last number of the Official Government Gazette published at Vienna contained the following announcement:

"Acting on the proposal of my Hungarian Minister a latere I, appreciating the great merits and work done for the Sixteenth International Medical Congress, confer on Dr. Coloman Müller, Member of the House of Lords, Director of Budapest City Hospitals, President of the Board of Health, the title of a Hungarian Baron, descending on his legal heirs; on Dr. Emil de Grósz, Professor in the University at Budapest and Director of the First Ophthalmological Chinic, the title of Hungarian Councillor to the Court; on Dr. Louis Vermes, chief physician, the title of Royal Councillor; on the Doctors Ignatius Bassa, sanitary inspector; Charles Jassniger, chief physician of the County

Workmen's Ambulatory; and Leo Liebermann, jun., first assistant in the Bacteriological Institute of the University, the Chevalier Cross of my Francis-Joseph Order.—FRANCIS JOSEPH."

THE council of the metropolitan counties branch of the British Medical Association has made arrangements to hold a meeting at which the three Direct Representatives of the profession for England and Wales on the General Medical Council, Dr. H. W. Langley Browne, Dr. H. A. Latimer, and Dr. L. S. McManus, will address their constituents who are resident in the metropolis and its neighbourhood. The meeting will be held on Monday, Nov. 22nd, at 4.30 P.M., at the St. James's Vestry Hall, Piccadilly, W. (close to Piccadillycirous). All members of the profession are invited to attend whether members of the Association or not.

THE death has been announced of Dr. John Waggett at Bournemouth. Dr. Waggett was in his ninety-first year, and has lived in retirement for over 20 years. He spent his professional life in practice in Kensington, and was an M.D. of the University of Edinburgh, as well as a Fellow of the Royal College of Surgeons of England. In 1855 he wrote a report on the cholera epidemic for the British Government.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies stated that 20 cases of plague with 15 deaths were reported during the week ending Nov. 4th.

Mr. C. O'Neill, M.D., M.Ch., M.A.O. R.U.I., has just been elected a Member of Parliament for the South Division of Armagh, Ireland.

WE deeply regret to announce the death of Mr. H. H. Clutton, senior surgeon to St. Thomas's Hospital, which occurred on Tuesday last.

Looking Back.

FROM

THE LANCET, SATURDAY, Nov. 12th, 1831.

Medical men, I have said, do not enjoy much of the patronage of these countries; and if the government did them bare justice, they would probably not be disposed to complain on this head. Other professions have not acquired much credit from their intercourse with the state and it is not likely that physicians or surgeons would be more fortunate. Of all individuals, indeed, the medical man should eschew politics. The Whig and the Tory, the radical and the ultra, stand in equal need of his assistance. (Excerpt from Introductory Lecture to a Course of Anatomy, by Arthur Jacob, M.D., Professor of Anatomy in the Royal College of Surgeons in Ireland. Delivered in the Hall of the College, Oct. 31st, 1831)

PRESENTATION TO A MEDICAL MAN.—At St. Stephens-in-Brannel, Cornwall, Mr. Donald Moore Barry, L.F.P.S., L.M. Glasg., L.S.A. Lond., was recently presented with a case of pipes from the members of the local branch of the St. John Ambulance Association as a mark of respect and esteem for his services as honorary lecturer.

THE ILLUMINATING ENGINEERING SOCIETY.—The opening meeting of this society will take place on Nov. 18th at 8 P.M. at the premises of the Royal Society of Arts (18, John-street, Adelphi, London, W.C.), when a brief report of the progress of the society will be presented by the honorary secretary and the inaugural address will be delivered by Professor Silvanus P. Thompson, D.Sc., F.R.S., the first President of the society.

THE STANDARDISATION OF DISINFECTANTS.

WITH SPECIAL REFERENCE TO THE DISINFECTANT PREPARATIONS COMMONLY SOLD TO THE PUBLIC.

A CHEMICAL AND BACTERIOLOGICAL INQUIRY.

In presenting our readers this week with the first instalment of a report on the standardisation of disinfectants we are fulfilling a promise given to them in THE LANCET of Feb. 6th, 1909, that the whole question of the standardisation of disinfectants should receive from us independent investigation.

The matter appealed strongly to us as one which in the interests of public health called for immediate consideration by scientific inquirers who had no connexion, direct or indirect, with the commercial side of disinfectants. Accordingly, no time was lost in appointing a commission and in drafting wide but simple terms of reference, with the result that actual practical work was commenced in the early spring.

This work has involved a very considerable amount of experimental inquiry in both the chemical and bacteriological laboratory. The results have been collected and are set in order in the following report, which we believe to be a contribution to the subject of the first interest and importance. For although no claim to finality in regard to the methods of standardisation outlined is made, yet the results, we venture to think, add considerably to our knowledge of the forces governing disinfection, while there have been brought to light in the course of the inquiry certain facts which should be of the greatest value in connexion with the practice of disinfection.

The bacteriological part of the inquiry has been entrusted chiefly to G. Sims Woodhead, M.A., M.D., Professor of Pathology in the University of Cambridge, who was assisted by Constant W. Ponder, M.A., M.D., M.R.C.S., L.R.C.P., John Lucas Walker Student at Cambridge. The chemical part of the inquiry fell chiefly to S. A. Vasey, F.I.C., F.C.S., Director of The Lancet Laboratory, who was assisted in the analytical work by J. E. Purvis, M.A., F.I.C., F.O.S., Lecturer on Chemistry and Physics in Relation to Public Health in the Chemical Laboratories, Cambridge.

THE NEED FOR STANDARDISATION.

The sale of disinfectants is in an unsatisfactory position in this country, and no official attempt has been seriously made to protect the public from employing an article which on examination may prove to be a disinfectant only by name. Yet the word "disinfectant" in the light of the germ theory of disease should now have an unmistakable meaning. The word "disinfectant" should mean simply and shortly a substance capable of destroying disease germs—a germicide, and anything which does not prove to be a destroyer of the activity of disease germs is not entitled to the name of disinfectant. It would be an advantage, we think, if the word "germicide" could be substituted for the word "disinfectant," and there would then be no confusion of terms. amongst which the words "deodorant" and "antiseptic" play their part, neither of which words connotes actual germ-killing power or real disinfecting property.

The fact that so far the State has not attempted to bring disinfectants within a system of control by which their germicidal efficiency could be guaranteed to the public may be attributed, we think, to the numerous difficulties which have attended both the chemical and bacteriological analyses of the complex substances

commonly sold as disinfectants. There are not wanting those who deny in the present state of our knowledge the value of either chemistry or bacteriology applied to the question of determining the practical value of a disinfectant. The chemical analysis of a disinfectant has certainly been freely discredited, if not ridiculed, as being a quite impossible criterion of the practical value of a germicide, and although it is natural to maintain that, after all, the determination of the actual germ-killing power of the disinfectant must be the only logical way of estimating its value, yet even bacteriological methods have been subjected to adverse criticism on the ground that laboratory results do not present a true picture of the practical state of affairs. The culture tube of the bacteriologist, it is argued, is a very different thing from the infected bed-pan, and the revelations of the test-tube of the chemist can have little relation to the events in a fever ward. Here, then, must be the starting point of inquiry.

Is it true that neither bacteriology nor chemistry can help us? Is it not possible to devise a method, whether chemical or bacteriological, which will enable us fairly to bring disinfectants under a legalised system of standardisation by which not merely the worthless may be distinguished from the valuable, but the weaker also from the strong? When such a method has been proved to give consistent results and to be relatively simple of execution, then the time has arrived to discuss the kind of legislative machinery which might be set in motion to ensure to the public the supply of disinfectants which disinfect.

It is obvious that if the domestic use of disinfectants is any good at all in preventing the spread of disease, there should be some security offered to the public that what they are buying is in reality a disease-germ destroyer. It is equally obvious that the employment of an inactive preparation may make the momentous difference as to whether disease is checked or spread. It will be admitted that the false sense of security which the use of a worthless disinfectant is calculated to give is a menace to public health and a direct incentive to the spread of disease.

It is the purpose of the present report to review the endeavours that have already been made to place the standardisation of disinfectants on a satisfactory footing. We give an examination of existing methods and point out probable errors which have arisen in the past, and the probable lines along which correct work may in the future be done with results possibly of practical value. It follows that the work embodied in the present inquiry has been taken up where previous investigators have left it.

Having regard to the foregoing considerations, it is obvious that our task of inquiry would resolve itself into two sections: I., the Chemical Analysis of Disinfectants; and II., the Bacteriological Examination of Disinfectants. We deal this week with the first section.

I.—THE CHEMICAL ANALYSIS OF DISINFECTANTS. DISINFECTION A CHEMICAL REACTION.

Reference has already been made to the fact that in many quarters no value is attached to the chemical analysis of a certain class of disinfectants on the ground that the results obtained throw no light whatever on the germicidal value of the compound. In other words, it seems to have been accepted that no relationship appears to exist between the chemical composition of a mixture and its germ-destroying power. This attitude on the face of it invites criticism, in view of the fact that definite chemical substances are known to exert a definite constant germicidal action. It is known, for example, that certain strength solutions of mercuric chloride or pure carbolic acid have a definite and constant germicidal power, and if that be the case then the germ-killing power is clearly a function of the mercuric chloride or carbolic acid It is simple enough to determine by chemical present. analysis the quantity of mercuric chloride or carbolic acid in the solution, and therefore to indicate in the results the germicidal value of the solution.

As a matter of fact, investigation has shown that a very complete analogy exists between a chemical reaction and the process of disinfection, one reagent being represented by the disinfectant and the second by the protoplasm of the bacterium. Further, Dr. Harriet Chick states that

¹ An Investigation of the Laws of Disinfection, by Harriet Chick, D.Sc.Lond., Journal of Hygiene, vol. viii., No. 1, January, 1908.

"the reaction velocity of disinfection increases with rise of temperature in a manner similar to that of a chemical reaction" and "it follows that there is a very great advantage in the use of warm solutions for practical disinfection." It is common knowledge that temperatare favours chemical reaction. Every practitioner knows that when testing urine for sugar, for example, the copper solution is not reduced in the cold and the red sub-oxide does not appear until the mixture is heated. If, then, disinfection is in the nature of a chemical reaction, it is interesting to inquire why the chemistry of certain disinfectants appears to throw no light upon their germicidal power. One explanation obviously may be that the present methods of chemical analysis are at fault, inasmuch as they fail to bring to light the exact chemical nature of the substance present, and may even fail to estimate its precise quantity. With complex mixtures containing the coal-tar acids we may be left in doubt as to whether analysis has been so perfected as to give a satis-factory qualitative, besides quantitative, account of the active agents present. On the other hand, the peculiar physical condition of some fluids, as, for example, the soapy and resinous emulsions of phenols, may accentuate the killing or chemical power of the disinfectant over the organisms. Dr. Harriet Chick and Dr. C. J. Martin have observed, for example,2 that the particles of an emulsion prepared by adding water to a soapy preparation of coal-tar acids exhibit active Brownian movement. The bacteria which were considerably larger than the mean diameter of the emulsified particles were seen to be bombarded by the latter. The bacteria were thus frequently brought into intimate contact with particles of tar acids, the disinfectant was appropriated by the organisms, and the death of the latter was inevitable. From these results it is concluded that the appropriation of an emulsion of tar acids by bacteria is in the first instance a process of adsorption and not a chemical combination, and that disinfectants of this class possess superior efficiency, because owing to this adsorption the bacteria rapidly become surrounded by the disinfectant in much greater concentration than exists throughout the liquid. It is important to add, however, that the same property of adsorbing the particles of the emulsion is possessed by most organic particles, in consequence of which the germicidal value of this class of disinfectant is greatly deteriorated by the presence of particulate matter other than the organisms which it is desired to destroy. It has been stated, in fact, that in the presence of organic matter the value of phenol was barely impaired, while emulsified disinfectants were reduced to two-thirds and one-half of their original value. It is perfectly clear, how-ever, that a particular physical condition of a fluid axails nothing in the cause of disinfection unless there is present a chemical substance which is an active germicide. The case is analogous to the more effectual bleaching effect of peroxide of hydrogen when exhibited in an oil emulsion instead of in a plain solution.

It will appear already from the foregoing observations that possibly we may demand of a standard disinfectant that (a) it should contain a certain proportion of a well-known germicidal substance, and that (b) the fluid in dilution with water should exhibit active Brownian movement of the particles distributed in the mixture. These requirements, however, can only apply to a certain class of disinfectants—viz., the soapy, resinous, or emulsified mixtures of phenols or other germicidal agents, preparations, in fact, which form a milky fluid with water. It happens that these are just the kind of disinfectant preparations which are mostly used for disinfectant purposes.

THE EVOLUTION OF THE COAL-TAR DISINFECTANT.

By far the majority of disinfectants sold to the public are mixtures of varying quantities of phenolic bodies with inert tar oils, in many cases with soap and resins or other emulsifying agents such as gelatin or dextrin, &c. It is interesting to inquire into the reasons which have led to the adoption of this class of compound for general disinfectant purposes. Before doing so it is well to point out that they are not necessarily ideal fluids in the work of sanitation because they possess a smell disagreeable to many persons, and, though effective disinfectants, have absolutely no deodorising qualities. There is little doubt that the public attach considerable importance to a compound that has a strong smell, but, of course, this may be a false criterion and give rise to a

serious delusion. The modern practice of disinfection, however, demands chiefly germicidal power. The forerunner of the present series of emulsified phenol bodies which are now The forerunner of largely used for disinfection was, of course, carbolic acid. The use of carbolic acid as an antiseptic and disinfectant grew rapidly out of the researches of Pasteur and Lister, who drew attention to its marked germicidal power. Time was when crude carbolic acid could be bought very cheaply by the bucketful, and sanitary authorities distributed large quantities of the acid for general disinfecting purposes. So abundantly, in fact, was carbolic acid supplied and so easily could it be obtained that a considerable number of cases of poisoning arose by inadvertence as well as by intention. Carbolic acid figured very largely in the list of suicides, and it was this fact which led ultimately to the acid and its homologues being placed in Part II. of the schedules of poisons. Privy Council Order of July 27th, 1900, permits the sale without control of liquids containing less than 3 per cent. of carbolic acid or its homologues in disinfectants on the ground that such fluid is not a poison within the meaning of the Act. In a subsequent Order of 1902 it was required that liquid disinfectants containing scheduled poisons should be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, with a label giving notice that the contents of the bottle are not to be taken internally.

Attention was in the meantime turned to the higher phenols, of which cresol or cresylic acid is the best known example. The advantages which their application to disinfection suggested were that they were less poisonous than phenol and of greater antiseptic power, but they were also less soluble than carbolic acid. Creolin was, perhaps, the first successful attempt to present cresol in a form suitable for disinfection. It was dissolved in soap or alkaline resin, with neutral tar oils, the clear, syrupy fluid producing an emulsion when mixed with water. Later, similar preparations were made, of which it was stated that they were free from phenol and its homologues, and the so-called phenoloids or oils obtained chiefly from the condensations during the process of carbonising coke in close ovens were introduced. bodies resemble the phenols in certain respects. but they appear to be more of the nature of oxidised hydrocarbons, containing a larger proportion of hydrogen to carbon than the members of the phenol series and a less proportion than the members of the cresol series.

The introduction of these and related oils, generally classed as phenoloids, rendered possible the preparation of a series of products emulsified with soap, resin, or gelatin, or other bodies which were stated to give a maximum germicidal effect and a minimum toxicity. These preparations must still be sold in accordance with the order of the Privy Council just referred to, although, compared with carbolic acid, they are relatively speaking non-poisonous. We shall refer to the point again on account of its importance, but for the present we may simply remark that the comparatively non-poisonous character of these preparations is not connected with the fact that they form emulsions. An emulsion of carbolic acid might possibly be a more rapid poison than its solution. Many of them do not contain carbolic acid or even its homologues.

The question of chemical analysis only becomes complicated and difficult when such complex mixtures of tar oils, acids, soaps, and resins, or other emulsifiers have to be dealt with. It is simple enough to determine the quantity of mercury present in a solution of its salts, the active chlorine value of chloride of lime, and so forth, but the separation of resins, soaps, or neutral hydrocarbons in a fluid which forms an emulsion with water is a difficult and uncertain matter. Further, it is desirable to discover the nature of the germicidal substance present, as, for example, whether it is carbolic acid, cresylic acid, or one of the phenoloid bodies already described. If this could be done with some degree of accuracy there can be no doubt that the results would be sure to throw some light on the probable germicidal power of the preparation.

CHEMICAL METHODS OF ANALYSIS APPLIED TO PHENOLIC EMULSIONS.

So far as we have examined the literature on the subject, there does not appear to be any method of separating the constituents of the modern emulsified disinfectant which can be regarded as at the same time trustworthy and convenient in operation. We believe that this unsatisfactory position is largely responsible for the view that the chemical

² Journal of Hygiene, vol. viii., No. 5, 1908.

analysis of coal-tar disinfectants has apparently afforded no interpretation of the question of their actual germicidal value. If, however, we admit that the method of analysis is at fault and that the results cannot be trusted, it is obvious that no data have so far been presented which can be used. Nothing is more certain than that we can estimate the exact amount of chlorine in bleaching powder or of mercury in a solution of corrosive sublimate, and since disinfection has been shown to be analogous to a chemical reaction between reagent and organism the power of these substances to destroy the organism must have some relation to the amount and kind of reagent present.

In regard to this matter an appeal might reasonably and profitably be made to those who have had large experience in the manufacture of disinfectant fluids. It is perfectly plain that makers know exactly what they use in compounding these more or less complex fluids. They must know their exact composition; they are the agents of the synthesis. They must know in particular what germicidal substance is present, whether it is carbolic acid, cresylic acid, phenoloid, or other body. They also know the proportion of this substance, and the amount and kind of emulsifying agent present, together with any oily vehicles in the form of hydrocarbons that may have been used. In a word, the manufacturer knows, or can know, if he chooses, the chemistry of his disinfectant goods. He takes care, also, to have its germicidal strength measured. He is thus in possession of the data required to co-relate, if that is possible, chemical composition with germicidal efficiency. We make no doubt that how to comply with any required bacteriological strength by chemical adjustment is no secret. We therefore maintain that a chemical method of examination, if it can be shown to give reliable results, should be of the utmost importance, if, indeed, it is not found to give ultimately a decided clue to germicidal power.

Several months' constant work in THE LANCET Laboratory convinced us of the unsatisfactory state of the existing methods of analysis. If they were not entirely untrustworthy they were exceedingly inconvenient, tedious, and troublesome. It was determined, therefore, after a careful reference to the literature on the subject, to work out a method for ourselves with the results about to be described.

Methods of analysis which depend upon the distillation of relatively large quantities of disinfectant are only suitable for the technical laboratory. The operations entailed are certainly not convenient in a public health laboratory. Methods which depend directly upon separation by solvents, like light petroleum, ether, acetone, and so on, offer many objections and their accuracy may be doubted. The separation of the solvent is not always a precise occurrence, and when that chances to be the case there is doubt as to the unalloyed state of the substance contained in the solvent. In addition, no attempt is made to differentiate the kind of phenol body present, which is very important. The method which follows is due to the investigations of Mr. Vasey and seems to us free from obvious drawbacks.

THE LANCET ACETONE-BARYTA (L.A.B.) METHOD OF ANALYSIS.

(a) Fluids containing Scaps and Resins as Emulsifiers.

The conclusion which we have come to in regard to the analysis of phenol disinfectants compounded of emulsifying agents, containing soaps and resins, is that these latter bodies must be decomposed or rendered insoluble before complete separation of the phenoloid bodies in a pure state can be effected. This may be done by converting the soluble soaps or resins, which consist commonly of potash or soda, into insoluble combinations. For this purpose a strong solution of baryta answers most satisfactorily. Fortunately, also, phenol, cresol, and the phenolic bodies generally are soluble in the resulting alkaline solution. Doubtless lime could be used, but it is considerably less soluble in water than baryta. If a few grammes of the disinfectant, which is made by amalgamating phenol bodies with soaps or resin (the constitution of most disinfectants in the market), be first hydrolysed by stirring with water and then an excess of

baryta water added, the actual germicidal body is completely dissolved in the baryta, and there is a rapid separation of the resins or soaps in the form of insoluble baryta compounds. This method is available at once for the complete separation of the phenolic bodies from the soaps, resin, and neutral oils with which they have been compounded.

Filtration is easy, the filtrate containing the phenol bodies whilst the residue consists of the fatty acids, resins, and neutral oils. For the purpose of assaying a disinfectant for its phenolic contents or strength it is only necessary to examine the baryta solution. If it is desired to ascertain the quantities of fatty acids and resins present the employment of acetone enables a separation to be made of those bodies from neutral oils. The residue from the baryta when shaken with acetone yields up its neutral oils, but leaves the soap and resin in the form of a powdery barium compound; filtration completes the separation. The acetone can be examined for the neutral bodies contained in it, while the residue on treatment with hydrochloric acid gives free fatty acids and resin which may be taken up with ether, the ether evaporated, and the residue weighed.

This is the principle of the L.A.B. method which we have found to work well and which has furnished the results given in Table I. In practice the following lines were adopted: 10 grammes of the disinfecting fluid (presumably composed of phenol bodies, soaps or resins, and neutral oils) were shaken well with 100 cubic centimetres of distilled water. After adding 15 grammes of barium hydrate crystals the mixture was placed in a capacious conical flask attached to a reflux condenser, and kept for half an hour at 100°C. by immersion in a vessel of boiling water. The flask was shaken at frequent intervals. The mixture was next allowed to cool, the separated oils, soaps, and resins being well spread out with a glass rod. In most cases it was found that the baryta solution could be decanted almost clean without filtering, but it is better to pour it upon a moistened asbestos plug in a glass funnel, the funnel being attached to the exhaust tap of a water-pump. The residue in the flask was next washed with warm baryta solution and the whole passed through the filter. The filtrate was made to a definite volume (generally about 300 cubic centimetres). 50 cubic centimetres or more of this was treated in a separating funnel with hydrochloric acid, calcium chloride was added, and the liberated phenols were extracted and washed with ether. The ether was then evaporated in a tall flask beaker resting on the top of a metal plate kept at 100° F. A glass tube connected with the water-pump was suspended in the middle of the flask, so that ether vapour was replaced by a current of air and the whole evaporated without any separation or condensation of water. The residue, the phenol bodies, was weighed (col. 1, Table I.). It was then dissolved in caustic soda and an excess of a solution of bromine in soda added, the amount of bromine present in the solution being ascertained in a previous experiment (Koppeschaar process for estimating carbolic acid). The bromine was liberated by adding hydrochloric acid. The bromine absorbed by the phenol was thus found, and care was always taken to secure an excess of bromine in the liquid, the excess being measured by replacing it with iodine (adding a few crystals of potassium iodide) and determining the iodine by means of a deci-normal solution of sodium thio-sulphate. The amount of bromine which had combined with the phenol body was thus determined and calculated into its equivalent of carbolic acid (col. 2, Table I.) It is obvious that if the phenol body present is carbolic acid the percentage figure obtained in the bromine experiment will approximate to the percentage weight of carbolic acid found by drying the ether extractions of the acidified baryta solutions. is no agreement between these figures carbolic acid as such is not the germicidal agent present but one or other of its homologues or a phenoloid, the bromine absorption of these bodies being lower. When, in fact, the difference is wide, the conclusion may be justified that carbolic acid is absent. There were not many cases in which the bromine figure for carbolic acid agreed with the actual weight of the phenol body found, according to our examinations of the phenolic disinfectant fluids now extensively advertised to the public; and the conclusion is that real carbolic acid is not, as a rule, the basis of these preparations. But the most remarkable feature of all is that an ultimate consideration of the results of both chemical and bacteriological analyses showed that the wider the difference is between the actual weight of the phenol body found

The following, amongst others, have been consulted: Commercial Organic Analyses by Alfred H. Allen, F.I.C., F.C.S. (J. and A. Churchill, 1900), Vol. ii., Part II., in which are references to analytical methods by the following authors: Chas. Lowe, Koppe char. L. de Koningh, Messinger and Nortmann, C. E. Smith, S. B. Schryver, Riegler, Ditz and Clauser, Fresenius and Makin, W. Spateholtz; Disinfection, by Samuel Rideal, D.Sc. (London: The Sanitary Publishing Co., Limited, 1903); a paper by M. Wynter Blyth, B.A., B.Sc., F.I.C., read before the Chemical Congress, London, 1909, and published in the Medical Officer, June 19th, 1909.

and its carbolic-acid value based on its bromine absorption, the greater is its germicidal efficiency.

The residues after treatment with baryta, which are enerally of a treacly description when soap is present but hard and firm when resins are present, contain the neutral hydrocarbon oils, the fatty acids, and resins. To this about 200 cubic centimetres of acetone were added; separation gradually ensues, and the neutral hydrocarbon oils dissolve in the acetone, the soaps and resins being left After thoroughly rubbing down the insoluble matters with acetone, the acetone solution was filtered and the fatty acids or resins, as the case may be, washed with acetone and collected. They were next treated with hydrochloric acid and shaken out with ether, the ether evaporated, and the weight of fatty acids or resins was obtained (col. 3, Table I). It was found necessary to examine the acetone solution further in case some fatty acids or resins had passed into solution, but the neutral hydrocarbon oils were never directly determined by weight as oftentimes they proved volatile, and on the whole it was considered more satisfactory to record them as a difference after the other constituents had been accounted for. To the acetone solution was put a 10 per cent. solution of caustic soda and the mixture was thoroughly shaken, when about 20 cubic centimetres of petroleum (white spirit) were added to facilitate the removal of oils, and finally about 500 cubic centimetres of water. After shaking and standing, the aqueous fluid was drawn off and filtered through a wetted filter paper, and the filtrate was made acid

(5) and (6) alkalies (cols. 5 and 6); (7) emulsifiers other than soap or resins (col. 7); and (8) neutral hydrocarbon oils, &c., by difference (col. 8). In this category Nos. 1 and 2 are the most important factors, Nos. 3, 4, 5, 6, 7, 8 may be regarded as negative quantities so far as regards germicidal efficiency. It is useful, however, to determine their quantities as being so much bacteriologically inert matter, which may usefully serve as a vehicle.

The foregoing process was tested on a fluid made in THE LANCET Laboratory from materials representing those employed in commercial disinfectants. The left hand column below shows the actual composition (or synthesis) of the fluid, while the right hand column shows the results obtained by the acetone-baryta method (analysis):—

	Fluid made up lows:	as Composition Found Method.	Composition Found by Above Method.					
•	Per cent	. 1	Per cent.					
Carbolic ac id	30.90	Carbolie acid	31.50					
Reem		30.88 Fatty seids and resins Sods	29-60 (70-55					
Soap	20.58	Soda	1.05					
Water		Water	16-00					
Hydrocarbona	21.75	Hydrocerbons	21.85					

The bromine process gave 31 00 per cent. of carbolic acid.

It should be added also that in the case of one of the commercial preparations examined the kind and amount of the components used in its manufacture were known, and it was found that the results obtained by the L.A.B. method

A = Neutral oils and water only.

n = Dextrin.

 $\alpha = Gelatin.$

with hydrochloric acid, and exhausted with ether. On evaporation, the ether yields the resins or fatty acids which failed to be retained in the barium residue. The amount usually is small. The weight is added to the weight of fatty acids or resins previously found in the barium residue.

The water, if present, was estimated by taking 25 grammes of the disinfectant fluid and adding exactly 10 cubic centimetres of a 10 per cent. solution of sulphuric acid and then 25 cubic centimetres of petroleum (white spirit). The mixture was then thoroughly shaken and left to rest. When separation was complete the clear liquid below was drawn off into a narrow and accurately graduated glass cylinder and its volume read, the excess over the 10 cubic centimetres of aqueous sulphuric acid added being regarded as the water present in 25 grammes of the sample. The alkalies were determined by getting an ash and titrating with standard acid.

The following data were thus obtained by the foregoing procedure: (1) phenol bodies directly by weight (Table I., col. 1); (2) carbolic acid value of 1 by bromine absorption (col. 2); (3) fatty acids or resins (col. 3); (4) water (col. 4);

of analysis were for all practical purposes in agreement with facts.

(b) Fluids containing neither Scap nor Resens as Emulsifiers.

There are, however, disinfectant preparations on the market (as will appear in Table I.) which, the use containing phenols, or bodies resembling phenol, as a permicidal basis, are not made up with soap or resin. They are simpler preparations containing the germicidal agent brought into uniform suspension by means of gelatin or gum (see Izal (gelatin) and Okol (dextrin) in Table I.). In such cases the treatment with baryta is not necessary, there being neither soap nor resin to separate. It was found that these substances could best be examined by treating 10 grammes of the fluid with an excess of absolute alcohol or acetone which dissolves the phenoloid, but precipitates the gelatin or dextrin. The insoluble mass was thoroughly exhausted by rubbing down with successive washing of acetone and finally dissolved in water; then the solution was evaporated to dryness and the residue of gelatin or gum so obtained dried and weighed. The acetone or alc shol solution containing the phenoloids (and neutral oils if present) was next

1

shaken up with a 10 per cent. solution of caustic soda and diluted freely with water. Any neutral oils present were thus set free, the separation being promoted by adding 20 cubic centimetres of petroleum (white spirit). The alkaline solution was then drawn off and filtered and the filtrate made up to a known volume. Part of this was acidified and CaCl₂ added, the separated phenoloids were exhausted with ether, the ether was evaporated, and the phenoloid weighed as described previously. The phenoloid after weighing was dissolved in caustic soda and examined in regard to its bromine combination value, as set forth in the analysis of soapy and resinous fluids. The water in these preparations was determined in the same way described in the analysis of disinfectants containing soaps and resins, but a longer time was required for the complete separation of the water from the phenoloids and oils owing to the difficulty of breaking up the emulsions.

The application of the foregoing analytical methods to the chief disinfectant preparations found on the market is given in Table I. The examples there appearing represent the preparations widely advertised to the public, and in every case the samples examined were purchased in the open market. The following were examined:-

Izal.—Newton, Chambers, and Co., Limited, Thorncliffe, near Sheffield. The contents of the bottle measured 4 ounces, and the price fixed by the makers was 6d. Estimated cost per ounce. 150d. Okol.—The Sanitas Co., Limited, Locksley-street, Limehouse. The contents of the bottle measured 10 ounces, and the price fixed by the

contents of the bottle measured 10 ounces, and the price fixed by the makers was 1s. Cost per ounce, 120d.

Bactoz.—The Sanitas Co., Limited. The contents of the bottle measured 11 ounces, and the price fixed by the makers was 1s.

Estimated cost per ounce, 120g.t.

Estimated cost per ounce, 1'00:1.

Cofectant.—Edward Cook and Co., Limited, Bow, London, E. The contents of the bottle measured 8 ounces, and the price fixed by the makers was 10/d. Cost per ounce, 1'31d.

McDougalls M.O.II. Fluid.—McDougall Bros., 66-68, Port-street, Manchester. The contents of the bottle measured 4 ounces, and the price fixed by the makers was 4d. Cost per ounce, 1'00d.

Kerol.—Quibell Bros., Limited, Newark. The contents of the bottle measured 7 ounces, and the price fixed by the makers was 1s. Cost per ounce, 1'21d.

Lawes Fluid.—Lawes Chemical Co., Limited, Mark-lane, London, E. The contents of the bottle measured 6 ounces, and the price fixed by the makers was 6d. Cost per ounce, 1 00d.

Pearson's Antiseptic.—Pearson's Antiseptic Co., Limited, 15, Elmstreet, London, W.C. The contents of the bottle measured 8 ounces and the price fixed by the makers was 1s. Cost per ounce, 150d.

Zotal.—Burgoyne, Burbidges, and Co.. Coleman-street, London, E.C.—The contents of the bottle measured 32 ounces and the price fixed by the makers was 1s. Cost per ounce, 0.37d.

the makers was 1s. Cost per ounce, 0.37d.

Krysyl.—Baiss Bros. and Stevenson, 4. Jewry-street, B.C. The contents of the bottle measured 20 fluid ounces and the price fixed by the makers was 10½d. Cost per ounce, 0.52d.

Lysol.—Charles Zimmerman and Co., 9 and 10, St. Mary-at-Hill, London, E.C. The contents of the bottle measured 8 ounces and the price fixed by the maker was 1s. Cost per ounce, 1.50d.

Carbolic acid (crude).—Purchased at a chemist's shop in Cambridge, 25, Sidney-street. The contents of the bottle measured 10 fluid ounces and the price charged was 6d. Cost per ounce, 0.60d.

Carbolic Acid No 5.—Calvert's, Manchester. The contents of the bottle measured 8 ounces, and the price fixed by the makers was 1s. Cost per ounce, 1.50d.

Cost per ounce. 1-50d.

Jeyes fluid districtant (black label; purchased at a chemist's shop).—
The Jeyes' Sanitary Compounds Co., Limited, 64, Cannon-street,
London, E.C. The contents of the bottle measured 10 ounces, and the
price fixed by the makers was 1s. Cost per ounce, 1-20d.

Jeyes Fluid Districtant No. 2 (brown label; purchased at a grocer's
shop).—The Jeyes' Sanitary Compounds Co., Limited. The contents of
the bottle measured 10 ounces, and the price fixed by the makers was 1s.
Cost per curse, 1-20d.

Cost per ounce, 1-20d

Oyllin (crade) supplied in bulk half-gallon drum by the Jeyes Sanitary Cyllin (crade) supplied in bulk half-gallon drum by the Jeyes saniary Compounds Co., Limited. The price was 4s. Cost per ounce, 0.60d., based, however. on a bulk sample. A sample of "Jeyes Special Fluid Cyllin Disinfectant" was obtained which gave chemical results identical with those given by the bulk sample. The bottle contained 9 fluid ounces and the price charged was 1s. The cost per ounce of this retail sample, therefore, was 1.33d. and the cost of 100 units of phenolic bodies 11d.

Cyllin (meileat).—The Jeyes' Sanitary Compounds Co., Limited. The contents of the bottle measured 4 ounces, and the price fixed by the makers was Is. Estimated cost per ounce, 3d.

THE SIGNIFICANCE OF CHEMICAL RESULTS.

We believe that our results give a very fair statement of the chemical composition of the disinfectants enumerated. Assuming that to be so, is this chemical information of any We believe that if the results are carefully considered they will be found to possess a value which has not before been recognised. To begin with, the analyses, of course, show-what previous methods may have done-the proportion of active materials as compared with inactive materials present. Thus the phenolic constituents in the proprietary preparations will be seen to have as wide a range as from 5.13 to 66.27 per cent., while what may be

called the inert excipients (col. 9) (soap, resin, neutral oils, alkalies, water) range from 39.73 per cent. to as much as 94 87 per cent. These wide differences clearly affect the question of intrinsic value, for the phenol compounds may be taken to be the chief costly constituent present as compared with mere soap, resin, water, and hydrocarbon oils. If it should happen, to take a simple case, that 6d. is charged for 8 ounces of a disinfectant fluid which is found to contain 30 per cent. of phenol bodies, and the same price is charged for the same quantity of another fluid which only contains 10 per cent. of phenol bodies, the purchaser is getting much better value in the former case, assuming that the germicide is presented in both cases in its active form. The fact, however, of combining the phenols in such a way that their highest efficiency is obtained cannot add much to the cost of production of the disinfectant. Cols. 10, 11, and 12 in Table I. are of interest in showing the amount of disinfectant fluid sold for a given sum of money, while col. 13 shows the cost of a hundred units of phenolic. bodies, the figures being based on the percentage proportion of those present. It will be seen that there are great variations in the numbers. In the case of crude carbolic acid itself the cost of 100 units is $2\frac{1}{2}d$. The cost of 100 units of phenolic bodies in the case of proprietary disinfectants varies from 5d. to over 6s. There is clearly some anomaly here, unless it can be shown that germicidal action has no relation whatever to the proportion of phenolic bodies present, or unless it can be proved, in spite of any assistance which emulsifying agents may give, that the germicidal action of a fluid containing, say, 5 per cent. of phenol bodies, can be equal to that of a fluid containing five or ten times that amount.

Beyond the mere analytical results there are indications, we believe, that a successfully conducted chemical analysis will throw light upon the actual germicidal value of a preparation. Such ought to be the case, it might be thought, if we accept that disinfection is analogous to a chemical reaction in which the disinfectant and the germ are parties in the equation. We cannot pretend that the exact interpretation is at this stage apparent, but when we come to compare the chemical behaviour of the various phenolic constituents of disinfectants with the bacteriological findings we shall see that under certain conditions the carbolic coefficients calculated upon the results of bacteriological experiment appear to be indicated by certain chemical

We must, however, leave the full discussion of this most interesting and important question until next week, when the report will be completed by the presentation of the bacteriological section of the inquiry.

(To be concluded.)

GLASGOW UNIVERSITY CLUB, LONDON.—The members and friends of the Glasgow University Club, London, dined together on Nov. 5th with Lord Rosebery, as chairman, at the Gaiety Restaurant, Strand, London. Amongst those present were Colonel W. Babtie, R.A.M.C., V.C., C.M.G., Dr. S. H. Belfrage, Dr. M. G. Biggs, Dr. G. H. R. Dabbs, Surgeon-General W. L. Gubbins, Mr. W. G. H. R. Dabbs, Surgeon-General W. L. Gubbins, Mr. W. Sampson Handley, Dr. G. A. Heron, Dr. L. F. Knuthsen, Sir Shirley F. Murphy, Dr. G. Rankin, Mr. Charles Ryall, Dr. T. Dixon Savill, Mr. G. Templeton, and Dr. Leonard Williams. The toast of the evening; "The University and the Club," was proposed by Lord Rosebery, who referred to the "sprouting up" of new universities all over the country and hoped the result would influence the national destinies. He was doubtful as to the spacess of grafting on destinies. He was doubtful as to the success of grafting on to the universities of Oxford and Cambridge the newer technical schools, for in these developments they could not compete with the newer universities. The University of Glasgow was ancient but was also new from its union with the city of Glasgow. The University of London might attract from all the scattered portions of the Empire the students who would naturally come to the metropolis, but it could never be so closely identified with London as was Glasgow with its University. The University of Glasgow was sending out men all over the Empire, and there was not a place where there could not be found a graduate of Glasgow forming a centre of learning and civilisation and exercising an influence for public good. Other speakers were Professor W. P. Ker, for public good. Other speakers were Profe Canon Hensley Henson, and Mr. W. Lorimer.

SOME CONSIDERATIONS OF MEDICAL EDUCATION.

III.1

The Requirements of the General Medical Council as to Preliminary Scientific Education.—The Place of Biology in the Curriculum.—Instruction without Examination. English Conjoint Board and the Preliminary Scientific Subjects.

THE General Medical Council has been for many years aware that the curriculum of the medical student bade fair to be overloaded, and some ten years ago official notice was taken of the fact by the institution of a Committee on Preliminary Scientific Education, which committee, forming a Joint Committee with the Committee on Examination, reported to the Council in 1904 in very important terms. The committee obtained information from a very large number of licensing bodies and medical and scientific institutions, and as a result of summarising all the knowledge which it acquired it was able to state that no very great difference of opinion existed among any of the bodies concerned. As so frequently happens, the position of the London medical schools was not quite on all fours with that of the other institutions because the London schools, as forming parts of the University of London, intimated that they would reply through the University. The University, however, does not appear to have consulted all the schools, although there is no reason to suppose that had this been done the result of the inquiry would have been less uniform. The eight recommendations of the Joint Committee were-

1. That an examination in chemistry in order to be sufficient should comprise a written paper, a practical examination, and an oral examination.

2. That in respect of chemistry a synopsis of subjects should be issued by each licensing body and that the scope of the examination in chemistry should not fall below that which has been indicated in the enemistry snould not fall below that which has been indicated in the report of the visitors and has been generally approved by the licensing bodies.

odiles.

3. That the examination in practical chemistry should not be limited to simple qualitative analysis but should include easy preparations and simple experiments illustrating important principles.

4. That an examination in physics in order to be sufficient should comprise a written paper and an oral examination, the latter to include practical questions on the use of physical instruments and

5. That in respect of physics a synopsis or syllabus of subjects should be issued by each licensing body and should include the elementary mechanics of solids and fluids and the rudiments of heat, light, and electricity

electricity.

6. That elementary biology should be retained in the curriculum.

7. That an examination in elementary biology in order to be sufficient should comprise a written paper and an oral examination, the latter to include practical questions on specimens and dissections and on methods of microscopical investigation.

8. That, in respect of elementary blology, a synopsis of subjects should be issued by each licensing body.

Until the sixth recommendation was reached the views of the committee were adopted by the Council with unimportant verbal alterations, and indeed one or two of the recommendations were reaffirmations of resolutions which the Council had already decided by vote at previous debates. But around the sixth recommendation "that elementary biology should be retained in the curriculum" an interesting debate arose. This debate was started by a proposal of an absolutely novel character made by Dr. John Yule Mackay, who proposed for the consideration of the Council an amendment in the following words :-

That the Council is of opinion that while the subject of biology should That the Council is or opinion that while the subject of bloogy should be retained in the curriculum it will not regard it as necessary that a prefessional examination in the subject should be demanded, provided the student has attended and duly performed the work of a satisfactory course of instruction in the subject as part of his curriculum at a university or duly recognised school of medicine.

Dr. Mackay, speaking in support of his amendment, placed biology in a different position from that of chemistry or physics. He pointed out in an interesting speech that the amount of work which the student was now compelled to do

in biology and in State medicine was heavy and growing heavier, while more attention also had perforce to be paid to the details of many branches of medical studies—he instanced mental diseases and ophthalmology-wherefore he considered that, if it was granted that the curriculum must be lightened, it followed that it was in the preliminary scientific subjects that the change must come. He thought that the principle of having subjects in the syllabus upon which it was possible that the students would not be examined might relieve the overcharged curriculum and the principle suggested in the first instance for biology might be extended in other directions.

The amendment was seconded by Sir John Batty Tuke on the ground that it brought to the notice of the Council a principle "which would tend to reduce the amount of weary grind that went on and resulted in no intellectual activity and the acquisition of the minimum of knowledge," and as far as his remarks were levelled against the abuse of the examination system, he was undoubtedly expressing the opinion of most of the medical profession and very many teachers and examiners. The Council, however, was divided as to the advisability, or even the possibility, of laying down that a subject should be a subject of teaching and not of examination, and it is difficult not to anticipate that if a subject were explicitly excluded from examination by the Council it would very soon be excluded from study—at any rate, the classes in it would come to be attended only on compulsion and in a perfunctory manner. Sir William Thomson made this point in his contribution to the debate. While admitting that year by year the work of the medical student had piled up until it was becoming more and more evident that five years were quite insufficient to enable him to master the details of his training, he held that if biology was only to be an instructional course there would be difficulty in saving it from becoming a farce. The whole of the Council considered that elementary biology in some form or another must be retained in the curriculum, although there were divergences of opinion as to the precise meaning of "elementary biology," a situation which induced some members to urge that the Council should lay down a minimum syllabus of biology, and which equally justified other members of the Council in declining to attempt what they considered an impossible task. Eventually Clauses 6, 7, and 8 were approved of by the Council, while Dr. Mackay's proposal reached this position that the Council instructed the Education Committee to collect information and report on the subject of the feasibility of retaining certain subjects in the curriculum without requiring examination upon them. We shall see later what became of this instruction.

The debate showed clearly that the Council, upon information derived from representative educational and examining bodies, was not prepared to recommend any lightening of the curriculum as far as the preliminary scientific subjects were concerned. There must be written and oral examinations in physics, and every student must be prepared to be examined in biology. While there was a tacit agreement that the curriculum was overloaded, the lightening of the load by throwing biology overboard or by making the instruction in chemistry and physics less important was not found in keeping with modern or progressive ideas of medical education. And at this juncture, at the same meeting of the Council, there occurred a second interesting debate, started in a totally different manner but covering much of the same ground and dealing with many of the same questions, inasmuch as the adoption of the recommendations of the Joint Committee by the Council may be regarded as an acknowledgment by the Council that the admittedly overcrowded condition of the medical curriculum could not be met by any modification of the preliminary scientific courses.

 $^{^1}$ Nos. I. and II. were published in Ter Lancet of Oct. 23rd (p. 1232) and 30th (p. 1301), 1909, respectively.

The other obvious alternative was to reconsider the length of the curriculum or the possibility of arranging the subjects within the curriculum in some more flexible manner. The practical action of certain institutions, notably the Conjoint Examination Board of the Royal College of Physicians of London and the Royal College of Surgeons of England, had this possible reform in view. The situation which was revealed at this debate more than four years ago remains unchanged, and may be considered as the middle stage of a dispute which had its origin in 1890 when the medical curriculum was lengthened to five years; and that the points at issue remain unsettled may be realised by a leading article which appeared in THE LANCET,2 having special reference to the views expressed by the science masters of public schools assembled in conclave to protest against the non-recognition by the General Medical Council of their teaching.

When the five years' course was instituted in 1890 it was not contemplated that the preliminary sciences should be studied elsewhere than at recognised schools of medicine or science. But the Conjoint Examining Board in England from a very early period exercised its discretion under the charters of the Colleges and granted recognition of the science courses given at many schools, and the Board continues to do this despite the regulations of the General Medical Council which are held by the Colleges not to override their privileges. Whether if the wording of the regulations had been different, so that the authority of the General Medical Council had been expressly set out, the Colleges would at the time have resisted it is not easy to guess, but the vagueness of the language employed in the earliest regulations affecting the five years' course undoubtedly conduced to the awkward situation which has arisen. Probably the Council at the time had not even contemplated the possibility of the medical curriculum proper being commenced at any secondary school, or anywhere save at certain universities, medical schools, and scientific institutions. As soon as the flaw was seen an amending resolution was passed containing a new regulation, to come into effect on Jan. 1st, 1900, to the effect that no medical student should be registered until he had commenced his studies at a school of medicine or at a scientific institution recognised by one of the licensing bodies and approved by the Council. The Conjoint Board in England refused to be bound by this regulation, and continued to recognise the instruction given in various schools in the preliminary scientific subjects as sufficient to admit students to the preliminary scientific examinations of the Board. That is to say, that schoolboys were able to count part of their schooltime, when they were presumably engaged upon their general education, as part of the statutory five years of the medical curriculum. The Council then asked for a return from all the teaching institutions recognised. with the object of finding out whether they were sufficiently equipped for teaching and whether the instruction given was adequate in amount. The return, which has been printed in the Council's minutes, showed that the teaching given was, in the opinion of the Council, of an unsatisfactory nature. Biology was taught in very few schools. As to chemistry and physics,

The course of instruction followed in most of the schools is less than 15 hours a week; in many it is very much less. And it is evident from the statistics presented that in some of the cases it is actually possible for six months of medical study to be constituted by a course of instruction in chemistry and physics, limited, so far as these subjects are concerned, to four or five hours a week, taken out at an ordinary grammar school during school hours, or at a technical institute, it may be in its evening classes.

The Council then decided to inspect the first professional examination of the Conjoint Board in England and that of

other bodies which had followed the example of this Board in recognising school work as part of the medical curriculum. Following on the inspection of the examination the two subjoined resolutions were passed by the Council on July 15th, 1903:—

(1) That the examination in chemistry, physics, and biology of the Examining Board in England is in the opinion of the General Medical Council insufficient. (2) That the courses of study in chemistry, physics and biology in many of the teaching institutions which have been recognised by the Examining Board in England, but not approved by the Council, are in the opinion of the General Medical Council insufficient.

Similarly the examinations of the other bodies recognising school work were found to be insufficient.

The Council then proceeded to define its requirements with respect to chemistry, physics, and biology, instructing each body to draw up a syllabus showing the course of study demanded and the subjects of the examination in each of the sciences. The English Conjoint Board drew up a new and greatly extended syllabus demanding from its students:—

This was the position at the meeting of the Council on May 28th, 1904, when Dr. Norman Moore moved that the communications between the General Medical Council and the Executive Committee from the English Royal Colleges in regard to the curriculum and examination in scientific subjects should be received and entered on the minutes. The course of instruction and details of the first professional examination which it was intended to incorporate in the regulations of the Cojoint Board for the future made it quite clear to the Council that, although the Royal Colleges did not admit in any way that legitimate fault could be found with their curriculum, they were prepared to demand. from their students a minimum course in chemistry, physics, and biology which ought to be sufficient for the acquisition of the elements of those sciences, that they were prepared to examine the students by paper and by viva voce and to demand a fair standard of marks from the candidates. The Colleges, however, proposed that the courses need not run concurrently, need not be completed within one year, could be attended before the preliminary examination in general education was passed, and could be undertaken at any properly equipped school, while counting for not more than six months of the curriculum. That is to say, the Colleges, relying on (1) the prestige of their charters, (2) the admittedly admirable nature of their test examinations, and (3) the absence of any definite right on the part of the Council to demand registration of every medical student as a proof of the commencement of medical education having taken place at an institution approved by the Council, intended to sanction the education of their students in the preliminary sciences at any place which seemed good to them. Regarded in one way, this was to resist the Council; regarded in another, it could be considered as a definite effort to lighten the burden of the student, for it enabled him to enter a medical school practically ready to attack anatomy and physiology at once.

(To be continued.)

MEDICAL MAYORS AND MUNICIPAL HONOURS.—Up to the time of going to press we have been notified that the following members of the medical profession have bee, elected mayors of their respective boroughs: Aldeburgh Mrs E Garrett Anderson, M.D. Paris, L.S.A. (re-elected); Lymington, Mr. Edward F. Chinery, F.R.C.S. Edin, L.R.C.P. Edin, M.R.C.S. Eng.; Newark, Mr. F. H. Appleby, M.R.C.S. Eng., L.S.A.; Oswestry, Mr. R. de la Poer Beresford, M.D. Glasg., L.R.C.P., L.R.C.S. Edin., L.R.C.P. Lond.; St. Albans, Mr. E. H. Lipscomb, M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond.; Wolverhampton, Mr. J. Grout, L.R.C.P. & S. Edin., L.F.P.S. Glasg.

² THE LANCET, Jan. 30th, 1909, p. 332.

THE MOTOR EXHIBITION AT OLYMPIA.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

THE only International Exhibition of Motors to be held this year opens to-day (Friday) at Olympia, and as London is distinctly becoming the motor mart of the world the importance of the exhibition can scarcely be exaggerated. Since last year the large annexe at Olympia has been thrown into the main hall, and the building now forms one vast space in which some 600 motor-cars are displayed. Some people, the minority probably, say, "What is the use of visiting the show? It is true we think of buying a car, but when we have found out the names of some of the best cars we will go to the manufactories and see them there." This, of course, is possible, though some of the factories are a good way off; but it seems to me that a dozen long journeys to distant and near makers can never give the general ideas to be obtained by the three miles' walk which a visit to each stall at Olympia entails. Here are all makes of cars, engines, and accessories, and the would-be owner of a car can easily see what sort of car he can obtain for the cheque he has decided to write. The impression that most visitors will get at Olympia is that nearly all manufacturers are now catering for the man of moderate means, which I think includes the majority of the medical profession. The chief thing we all require is some form of carriage which, when the occasion demands, can be depended upon to start at once and to transport the owner from patient to patient, and to do this quickly and also economically, without vibration or noise.

A preliminary inspection of Olympia early this week confirmed my view that this, the eighth show held by the Society of Motor Manufacturers and Traders with the cooperation of the Royal Automobile Club, is much like its predecessors, only larger, with more temptations to the motorist to dispose of his present car and to indulge in one of the many and inviting new ones. Of course, the question on everyone's lips is, "Which is the best car," and naturally medical men ask, "Which is the best one for us?" The tastes of medical men vary from the lordly six-cylinder beautifully upholstered limousine to the very modest twoseated 6 h.p. single cylinder, with a Cape cart hood and a front glass or mica shield. A practitioner's income has, of course, much to do with his choice of a car, and the character of work expected of the car must also be taken into account.

The space at my disposal does not allow of an exhaustive treatment of the exhibition, but I have selected for notice this week some cars and other exhibits which appeared likely to interest a medical man, and next week other cars as well as the general features of the exhibition will be considered.

The Adams Manufacturing Co., Limited, show on Stand 145 their 10 h.p. single-cylinder car, with their planetary evermeshing gears and interlocked pedal control. Their new model has a four-cylinder engine, and can be supplied either with a standard gate-change four-speed forward and reverse gearbox, or with the ever-meshing gears as on the single cylinder.

Messis. Argylls, Limited, have an interesting range of cars on Stand 65. Some particulars of the productions of this firm were given in THE LANCET of May 30th, 1908, and August 21st, 1909. The cars which they are exhibiting are in every way up to date and worthy of the name of this oldestablished firm.

Messrs. Sir W. G. Armstrong, Whitworth, and Co., Limited, show on Stand 42 two 12-14 h.p. cars which are well worthy the attention of those seeking a small four-cylinder. The cylinders are of 80 mm. bore by 120 mm. stroke, cast en bloc with ample water jackets, the valves being all on one side and of large dimension. A good feature is that the crank shaft is supported in the upper half of the crank case, so that the lower half, which is detachable, acts only as a cover. The inlet and exhaust pipes are arranged on the opposite sides of the cylinders, and a special point which is claimed is that the inlet gases pass through the inlet valves through passages cast in the cylinders, and are thus warmed before reaching the combustion chamber. Unlike most monobloc engines, the exhaust pipe is cast separately and four-cylinder being well worthy of inspection, as it has has four outlets, one for each cylinder. Lubrication is by a been improved since it was brought out last year. The wheel

gear-driven pump in the crank case, and through ducts in the crank shaft to the main bearings. Cooling is on the thermosyphon principle, and vanes in the fly-wheel act as a fan, and suck air through the honeycomb radiator. The clutch is of the multiple disc pattern, self-contained in an oil-tight casing, and a universal joint is interposed between the engine and gearbox. Four speeds forward and a reverse are provided, and, as is now the custom, the casing of the back axle takes the weight of the car, and the inner or live axles merely take the drive. The throttle is worked by a lever on the right hand of the steering wheel or by a foot accelerator pedal. The car can be had with a wheel base of 9 feet 2 inches or with one a foot smaller.

On Stand 69 the Austin Motor Company, Limited, show two cars which are bound to interest medical men. 7 h.p. two-seater is an entirely new single-cylinder model. The bore is 4s inches and the stroke 5 inches, and both valves are on one side. Lubrication is by a pump in the crank case. A commendable feature is that two separate ignitions are fitted, and cooling is by thermo-syphon. Change speed is of the gate type, and the top speed is direct to the live axle. The propeller shaft has a universal joint at each end. As this car is built by one who was manager of the firm that built the successful little 6 h.p. Wolseley, it certainly is worthy of inspection by all in search of a small car. 15-h.p., which is shown as a landaulette, should be popular with town practitioners. The engine is under the driver's seat, thus permitting a roomy carriage with a wheel base of only 7 feet 9 inches, so it is easy to manœuvre in traffic. A 40 h.p. caravan is also shown, with a saloon to dine six people and a kitchen attached, in which a full-course meal for that number can be prepared. For patients desiring open-air treatment I cannot imagine a better vehicle, for every accommodation is provided for sleeping and lavatory purposes.

Belsize Motors, Limited, have on Stand 83 a variety of their 14-16 h.p. cars, of which the special features are four-cylinder engine, pump lubrication, thermo-syphon cooling, Bosch magneto ignition, metal-to-metal clutch, three speeds forward and reverse, with a gate change. With a standard touring body the price is £290, and with a landaulette £390.

Messrs. E. H. Bentall specialise in one chassis, of which they have four specimens on Stand 26. The special points are single unit gearbox, propeller shaft and back axle, a fibre-to metal clutch running in oil, and all the four brakes act on the road wheels direct. The valve mechanism is very simple, and is situated on top of the engine.

Messrs. Brown Brothers, Limited. on Stand 133, show their 20 h.p. four-cylinder landaulette, which has separately cast cylinders, magneto and accumulator ignition, pump lubrication, internal coned clutch, four speeds, with the gate system of change levers, and certainly is wonderful value for the price asked, £395. The "Albruna" 10-12 h.p. four-cylinder has its cylinders cast all in one piece, an automatic carburettor, magneto ignition, and foot accelerator, with auxiliary hand adjustment on the dashboard, and is priced at £240 as a two-seater and at £270 with a side-

entrance body.

On Stand 39 the Clement Motor Company have three specimens of their 14-18 h.p. car, the specification of which provides a frame of pressed steel, three-quarter elliptic outhung rear springs, four-cylinder engine, 85 mm. 120 mm., Bosch high-tension magneto ignition, lubrication by gear-driven pump, White and Poppe carburettor, leatherfaced cone clutch, tension spring easily accessible for adjustment, gate sytem of gear-changing, and transmission through cardan joint with metal-encased universal joints.

The Connaught Motor and Carriage Company, Limited, show a fine 14-20 h.p. Renault, with a cabriolet body, also a Siddeley with a double Victoria body, and another Siddeley as well as a 15 h.p. Talbot, with their three-quarter landaulette. These are on Stand 107. This firm is sole concessionaire for Messrs. Léon Bollée, who have brought out a new light four-cylinder 14 h.p., with engines cast in pairs, thermo syphon cooling, mechanical sump lubrication, and a gate-change speed. Three of these are on Stand 32, and one with a Connaught torpedo body struck me as exceptionally comfortable. They also stage on Stand No. 31 specimens of the Nene Automobil Gesellschaft, the 14 h p.

base is now longer, the clutch is improved, the front brake is of larger diameter, and the speeds are now worked by the popular gate-change.

The Daimler Co., on Stand 36, introduce for the first time their 15 h.p. valveless engine car, their larger model having given not a little satisfaction since its appearance at the last exhibition. The distinction lies in the fact that the engine has no valves in the ordinary acceptation of the term—that is, no mushroom valves operated by a cam shaft. Instead, the piston is enveloped by two open-ended shells, surrounded by the cylinder casting, these shells being worked up and down by a kind of miniature crank shaft. Running parallel to the crank shaft and revolving off it by a silent chain in the shells are ports, which are covered or uncovered by the sliding of the shells over one another and in the cylinder, and thus the cylinders are filled and scavenged, compression being maintained by a "junk ring"—a wide ring at the bottom of the head from inside the piston. These cars are bound to attract attention, and if visitors are unable to get near the Daimler exhibit a section of the Knight's patent engine can be seen on the stand (44) of the Minerva Motor Company, who turn out a 16 h.p. car fitted with a silent Knight engine, and show a chassis, a side-entrance car, and a landaulette.

Messrs. Darracq and Co. show on Stand 62 various types of bodies of their new 14-16 h.p. four-cylinder car, which was described in THE LANCET of Oct. 30th, p. 1303. With a standard double phaeton body the price is £225, and a doctor's coupé, in which the owner-driver can manipulate completely protected from the weather, is turned out at

275 guineas.

Five different models form the exhibit on Stand 60 of Messrs. De Dion Bouton. This firm were one of the first to popularise motor-cars among the profession, and their productions are probably as great favourites to-day as when they were introduced. The 8 h.p. one-cylinder is the up-to-date representation of their original 6 h.p., but, of course, it differs. The bore is 100 mm. and the stroke 120 mm., the inlet valve is mechanically operated, ignition is by high-tension magneto, the drive is direct on the top speed, it has a live back axle, and ball-bearings to all the wheels. The one shown has a two-seated phaeton body of convex shape, with high side doors, hood, and wind shield, and, like its early predecessor, it is sure to attract many purchasers. The 14 h.p. four-cylinder is similar to the 12-14 h.p. of last season, but the stroke has been increased by 20 mm. It is fitted with a new combination landaulette, comprising a double Victoria touring body with a sort of Cape-cart hood which, with glass windows, forms a perfect landaulette, and should interest all who desire an open car which the owner can drive, combined with a closed carriage. A 14 h.p. chassis, with sections cut out to show the construction and working of all the inner parts, should be seen. It is quite an education in motor anatomy. The most important departures from previous practice with this firm is the fitting of live axles to the two lightest models and the suspension of the differential on a tubular stav isolated from the frame by eight rubber buffers. On their highest-power car an eight-cylinder V type engine is fitted. Except on the 8 h.p. lubrication is forced by a pump. The clutch is of the non-lubricated three parallel disc plate type and sliding gears are now used. These are, of course, now the fashion, but beginners may regret the "fool-proof" expanding clutch-ever-in-mesh variety.

Messrs. S. F. Edge stage on their stand four noiseless Napier cars, which are sold with a three years' guarantee. Full details of these cars were given in THE LANCET of Oct. 9th, p. 1092. They are undoubtedly worthy of serious consideration by those in search of a reliable, well-built

carriage.

Germain cars are shown on Stand 28—two 18 h.p. and one 20 h.p. The important features of the 1910 models are positive pump lubrication, gate-change speed, metal-tometal clutch, steel cylinders, and brass water jackets.

Most of these exhibits have torpedo bodies, which have been introduced by Captain Theo Masui, the agent-general for the Germain cars.

Messrs. H. M. Hobson, Limited, have on Stand No. 25 three Delahaye cars and one Hobson car. Of the former, the 12-16 h.p. and the 9-11 h.p. are both well suited for medical men. On their accessory stand, No. 212, they show the new type Hobson-Pognon magneto plug. The Claudel-Hobson carburettor, which was described in THE LANCET

of July 4th, 1908, p. 44, is on view, both as a complete model and in sections. A novelty here is the Hobson tyre clamp. This clamp entirely obviates the use of security bolts, and the necessity of nipping the inner tube when it is being fitted; and, of course, saves considerable time and labour when tyre troubles occur. In fact, it makes the removal and fitting of the tube an operation which can be performed within a few minutes. This clamp can be employed with any existing cover, and no special inner tube is necessary. Another useful little article is the Bougie switch for locating engine morbidities without the necessity of removing the plug, or using a screw driver or other unsatisfactory instrument for testing, thus obviating the chance of

damaging either the magneto, coil, or accumulator.

Messrs. Charles Jarrott and Letts, Limited, have on Stand 45 two 12-14 h.p. Crossley cars, the productions of Crossley Bros., Limited, of Manchester. The special features of these are monobloc engine, all valves and tappets enclosed, and high-tension dual ignition. The engine flywheel and gearbox form one self-contained unit, so arranged and designed, however, that the engine or the flywheel and gearbox portion can be removed from the chassis independently. The clutch is of the metal-to-metal expanding shoe-type running without lubrication. The gearbox gives four speeds forward and reverse through a pivoted gate, and the propeller shaft to the back axle is encased in a steel tube. terminating at the gearbox in a spherical ball forming an oil bath for the universal joint. This tube constitutes both a radius and a torque rod, so the back springs are shackled at both ends. Front wheel brakes operated by a foot pedal, and back wheel brakes controlled by a hand lever, are fitted, thus avoiding braking strains on the transmission. The exhibit also comprises three of the 12 h.p. voiturettes manufactured by Messrs. Sizaire and Naudin. This is the car described in The Lancet of March 27th of this year, but the engine has been increased in size and power, the bore and stroke now being 120 by 140 mm. instead of 120 by 130 mm. as in the 1909 models. Some of the working parts are now more accessible, and there is an improved method of adjusting the brakes.

Messrs. Morgan and Co., who are the sole agents for the Adler cars, have on Stand 58 some six specimens of these well-known German automobiles. The 12 h.p. has a four-cylinder engine, with a bore of 75 mm. and a stroke of 100 mm. Lubrication is mechanical and dual ignition is fitted. The clutch is of the metal-to-metal cone type, and the gearbox is close up against the clutch, thus dispensing with any need for a universal joint in the clutch shaft. The back axle is of the usual bevel drive variety. One of these cars is shown with a landaulette body, extension front, and Cromwell patent folding wind-screen, and another with a very neat two-seated body. Probably the chassis that will appeal most to doctors is the new 8 h.p., which has a slightly more powerful engine than the 7 h.p. of last year: otherwise the car is built on similar lines, and with a twoseated body should make an ideal car for the man who drives himself.

The London Motor Garage Co., Limited, on Stand 82 show various models of Charron cars, and especially recommend for doctors their 15 h.p. two-seated runabout fitted with an extra folding seat, and their 15 h.p. landaulette. This firm are prepared to sell these cars on the hire-purchase system or to enter into a contract for maintenance and all running expenses of a car.

Messrs. Lorraine, Dietrich, and Co. show their British-built car, a 20-30 h.p., on Stand 68, and on Stand 71 the exhibits hail from the original establishment at Lunéville. The 12 h.p. four-cylinder live-axle car, fitted with a threequarter landaulette body by Salmons, has a special lock, and is thus well suited for town use.

Messrs. Osborn and Co., Limited, have on Stand 29 9 h.p. two-cylinder and four 14-16 h.p. four-cylinder Gregoire cars. These models are practically the same as those shown last year, except that now the gate change speed is fitted in lieu of the quadrant type. There is a rumour that Automobiles Gregoire of Poisay are building a single-cylinder chassis which will be put on the market early next year, and probably at a price not far off £100. On this stand are some specimens of the Lynton resilient wheel.

Stand 59 will undoubtedly be frequented by many medical men, as the Rover Company have always been well patronised by the profession. Their little 6 h.p., which was described in THE LANCET of August 22nd, 1908, has been further improved, and is now fitted with two independent ignitions, high-tension magneto and coil and accumulator, and high entrance doors are provided. Their 15 h.p. landaulette, with metal-to-metal clutch, change speed quadrant through cardan shaft, 820 by 120 tyres, is handsomely upholstered and finished in every detail, and is in every way an ideal carriage. This car is also exhibited with a touring four-seater body. Specimens are also shown of their 12 h.p. and 8 h.p. cars.

The Star Engineering Co., who have for several years past specially catered for the motoring doctor, show on Stand 63 specimens of their 10 h.p., 12 h.p., 15 h.p., and 18 h.p. cars. A description of these vehicles and how they are built was given in THE LANCET of Feb. 20th, 1909.

The Standard Motor Co., Limited, have on Stand 53, in the centre of the show, an entirely new 12 h.p. model, with four cylinders 25 by 4½, wheelbase 8 feet, high-tension magneto ignition, thermo-syphon cooling, and horizontal cardan shaft, with worm drive. A 16 h.p. four-cylinder and two 20 h.p. six-cylinder cars are also shown.

A car that should not be missed is the Straker-Squire on Stand 46. This firm are specialising on one model, a 15 h.p. four cylinder, which is suitable for a two-seater, four-seater, or landaulette body, and specimens with these varieties are shown by them. In another issue I hope to give some details as well as the result of a trial run on this car.

The Swift Motor Co., Limited, are represented on Stand 66 by a couple of their two-cylinder cars—a two-seated body and a side-entrance body. They also have a four-cylinder 15-18 h.p. and one of 18-24 h.p. But the car on their stand which will, I think, appeal to the profession is their new single-cylinder model, a 7 h.p. two-seater, with pressed steel frame, thermo-syphon cooling, magneto and accumulator ignitions, leather-faced clutch, gate change, live axle, and completely enclosed brakes.

live axle, and completely enclosed brakes.

On Stand 38 John I. Thornycroft, Limited, show their 18 h.p. as well as their higher powered models. The 18 h.p. has four cylinders cast en bioc, forced lubrication to all engine bearings, thermo-syphon cooling, high-tension magneto ignition, metal-to-metal clutch, three-speed gearbox, direct drive on top speed, and the usual live axle. The petrol is fed to the engine by means of pressure taken from the exhaust. On one chassis is mounted a Victoria phaeton, with high front doors, hood, and glass wind-screen.

Messrs. Warwick Wright, Limited, have on Stand 74 various types of 12 and 18 h.p. Metallurgique models. The cylinders are not placed directly over the centre of the crank shaft, but are set to one side, which enhances the power of the motor. The clutch is of the metal-to-metal type, on the principle of the internal expanding brake. Gatechange is fitted, and the writer was so impressed with these productions that he hopes shortly to give a detailed description, together with his experiences of a run on their 12 h.p. Doctor's Car. The one shown is fitted with most luxurious body-work by Messrs. Vanden Plas of Brussels.

The Wolseley Tool and Motor Car Co., Limited, have on Stand 43 various cars. One especially suited for a doctor's requirements was fully described in The Lancet of Sept. 11th, 1909, only now a considerable number of improvements have been effected. On the new 12-16 h.p. a disc clutch is used, with double universal joints between it and the gearbox, and the drive is by a worm instead of a bevel gear. Another refinement is that the front hubs have Timken roller bearings, which are tapered, and consequently adjustable for wear. The 16-20 is an endeavour to further improve the 14 h.p. mentioned in The Lancet of Sept. 11th. The engine has a longer stroke and all the improvements common to the new 12-16 model. Any kind of body can be fitted to this model, including a town carriage.

The Show is rather like a pudding—a rich one, too, nearly all plums and but little suet. So that, provided the would-be purchaser knows the limit of his purse and what he wants of his mechanical mount, he should find it easy to pick a decent plum from amongst the collection. The great thirg for the medical man, I hold, is not to be too ambitious, not to be too anxious to have a more powerful automobile than is necessary. For the man who drives himself a light two-seater, such as a 6 h.p. Rover, 7-9 Darracq, single-cylinder Austin, small De Dion, little Star, two-cylinder Renault, Adler, or Swift, is hard to beat, while those who are prepared to spend more for initial outlay as well as for upkeep will find ample choice amongst the Armstrong Whitworth,

Bentall, Clement, Darracq, Brown, Napier, Enfield, Germain, Hobson, Sizaire and Naudin, Charron, Martini, Panhard, Star, Wolseley, and Vauxhall cars to suit their needs and purses.

Some considerable time occupied in examining carriage work must be reduced to a very few lines. Messrs. Maythorn show a very light and compact miniature limousine, also a coupé landaulette which encloses the driving seat and carries two people inside, besides the driver, and by means of a sliding driving seat the driver has plenty of room to get out on the "off" side behind the levers. Messrs. H. J. Mulliner have an entirely new design of two-seated body, with hood, screen, and high side doors. Landaulettes and limousine bodies are also shown by this firm and by Messrs. W. and F. Thorn, Messrs. Morgan, Messrs. Lawson, and Messrs. Thrupp and Maberly. Certainly in this Show there is a fine display of body-work, but I think a little more attention might with advantage be devoted to the angle of the seats. The cushions are soft enough and foot-rests and warmers are now provided, but those who have to sit in a car as doctors have would, I am positive, feel more comfortable if the backs of their seats were some two inches lower than the fronts. It may be laziness to sit in a tilted-up chair, but I know this: it is more restful than the one parallel to the floor.

Perhaps the most important accessory in connexion with a car is the ignition apparatus. In the gallery practically every type can be seen, and, what is more, many working models are exhibited, so the principles can be easily grasped. The Simms Manufacturing Co. on Stand 257 have their switch starters, which enable the engine to be started from the seat without the trouble of getting down and turning the starting handle. The Bosch Magneto Co. at Stand 192 have a novelty in a magneto capable of giving sparks at the rate Thomson Bennett, Limited, display of 12,000 a minute. on Stand 271 a magneto which has a small epicyclic gear between the drive and the machine, thus the armature can be moved for retard and advance, keeping the maximum position at all points. It is adapted for starting on the switch, without an accumulator. Messrs. J. C. Fuller and Son have working models of their dual ignition with switch starter. The Electric Ignition Co. exhibit improvements in coils, contact breakers, switches, and distributors, and the New Hall E.I.C. dual ignition system. The invention of Sir Oliver Lodge, a patent igniter known by his name, is on Stand 234. The High Tension Co., in addition to magnetos, have an electric horn, the sound of which is said to carry at least half a mile. On Stand 162 the United Motor Industries, among many electric appliances, show "La Magicienne," a dynamo for lighting motor-cars. From magnetos the attention is easily turned to ignition cables, and those thinking of re-wiring their cars will find on Stand 205 all sizes and kinds of rubber-covered and braided insulated wires, which are made by Messrs. E. Kalker and Co.

On Stand 178 Messrs. Longstreth's, Limited, show the Lithanode system of car lighting, by means of which the whole of the interior and exterior illumination of an automobile is supplied from a 4-volt accumulator. This entails a particular form of lamp, as the usual 4-volt lamp is insufficient for head- and side-lights. In the one employed, by means of an adjusting screen, the beam of light proceeding from the lamp is made either parallel or divergent, and the more the rays are contracted the greater the illumination. A complete combination accumulator is also exhibited, which is suitable for both cautery and lighting purposes.

On Stand 164 Messrs. André A. Godin and Co. show a comprehensive selection of lubricators, horns (including the Godin electric horn), piston pumps for oil circulation, jacks, tool outfits, and lamps.

Tyres are an expensive and certainly anxious matter to all who motor, and especially so to medical men, as a burst or puncture may be of serious import when on a professional round. Consequently each year the writer searches through the gallery for something new and cheap. Alas! this year there may be many improvements, but there is no improvement in the matter of price. The Palmer Tyre, Limited, manufacture their corded tyres by a most ingenious machine, which is shown in operation. They exhibit a new light type which is said to be so flexible that it can be fitted even without tyre levers. These are made with a three-ribbed tread, which is deeper than previously, so that they should run an increased mileage. This company also show on Stand 296 a

reliable device which loudly indicates loss of pressure in a tyre before it has become quite deflated. Still, if a sealomatic tube, such as is shown by Messrs. Liversidge, or one of the "Challenge" reinforced inner tubes be used, such an apparatus is not likely to be needed, as with the former, if a puncture occurs, a viscous substance on the inside of the tube fills up the puncture, while with the latter the tube is so protected that it is not likely to burst.

The Continental Tyre and Rubber Co., Limited, the Avon India Rubber Co., Limited, Gaulois Tyres, Limited, the Shrewsbury and Challiner Tyre Co., Limited, the B. F. Goodrich Co., Limited, Messrs. David Moseley and Sons, Limited, the Samson Leather Treads and Tyre Company, Messrs. Dunlop, Messrs. Michelin, and Messrs. Liversidge are all represented, and any of their goods should give satisfaction, provided the tyres chosen are of sufficient size in relation to the weight of the car, and are kept properly inflated and have all cuts filled in directly they occur. In this connexion the Harvey-Frost vulcanizer merits attention, as it is both a prevention and a cure for punctures, and by its means damaged covers and tubes can be quickly and thoroughly treated and rendered fit again for their respective duties. There is no doubt that the increased price of rubber and the corresponding higher cost of tyres are unfortunate for the motorist, but the reverse for the tyre repairing specialists. With tyres at their present price tyre economy is essential, and the appliances of Messrs. Harvey, Flost, and Co., Limited (Stand 207), are a help in obtaining the longest life out of a tyre. This firm have unqualified confidence in their apparatus, for they offer to loan one to any motorist for 10 days free of charge, and they also have special terms for the profession, which can be had on application at 27, Charing Cross-road. The Allen-Liversidge brake, which was fully described in THE LANCET of Nov. 14th, 1908, p. 1463, is shown. It is undoubtedly to a certain extent a preventive of side slip; and, what is also important, it obviates wear on the transmission gear and

On Stand 295 in the gallery the Midland Rubber Co., Limited, show the Ajax non-skid tyre, which is a combination of rubber studs and rubber ribs, with a row of metal studs running down the centre. It is certainly an insurance against skidding. They also exhibit a detachable rim, which can be exchanged quickly, the only tools needed for manipulation being the fingers.

The Kempshall Tyre Co., Limited, have on Stand 294 their ribbed non-skid tyre and their light anti-skid tyre. The latter has a round tread with rubber studs on the sides. Both are successful in obviating skids, and they have one advantage over the more certain metal-studded non-skids—they wear better and last longer. The Kempshall emergency patch is a useful accessory. It is sprung into a damaged cover, the tube is inflated, and then, to use their own descriptive phrase, it "always grips, never slips."

(To be continued.)

MEDICINE AND THE LAW.

The Relations, Past and Future, of the Medical and Legal Professions.

Sir John Tweedy, in his opening address delivered at the first meeting of the current session of the Medico-Legal Society, of which he is President, gives a very interesting sketch of the early history and development of medicine and law, as well as of medical and legal education (see p. 1435). It will be seen that he traces the course of these two learned professions, following paths not always parallel nor always of equal smoothness, from the classic periods of Athenian and Roman learning through the Middle Ages to the present day, which finds the Medico-Legal Society well established and doing useful work in the ventilation and discussion of questions interesting to both professions and of importance to the public. The Medico-Legal Society is to be congratulated upon the position which it has already attained, and if it ever succeeds in accelerating the change in judicial procedure suggested by Sir John Tweedy at the close of his address it will have good reason to be proud.

We refer to the possible employment of medical assessors to assist judges, and on fitting occasions to displace juries in cases in which medical evidence is laid before courts of law. The weighing of conflicting medical opinions is conducted under conditions neither satisfactory to the medical profession nor advantageous to the community. The jury is not to be lightly dispensed with, particularly in cases where the personal safety or the liberty of the subject is involved, but at the same time the jury never has been, and never will be, asked to decide all the matters at issue in a trial whether civil or criminal. Our meaning is that questions of law are argued before and decided by the presiding judge, and we submit that this is done not because law is a mystery revealed to a select few or a science beyond the grasp of ordinarily intelligent minds, but simply because such minds need to be trained in the science and practice of law before the points which arise in argument with regard to it can be properly weighed and distinguished. In like manner those trained in medical science may often put forward divergent opinions when called into the witness box, and the subject may be such that an eminent man of science after listening to both sides would find it difficult to arrive at a correct conclusion. He might be wrong in his view, just as a judge is found to have been whose decision is reversed on appeal. Nevertheless, scientific issues are left to be decided by a jury, under the direction of a judge, as "questions of fact," or they are adjudicated upon by a judge, a process which might be compared to that of leaving questions of law to be argued before a jury under the presidency of an eminent physician or surgeon, or at times before him alone. We have spoken above of the accelerating of a change, as if we believed that it were likely to be accomplished in process of time without the assistance of the Medico-Legal Society, and we would justify the expression by pointing to the appointment of medical referees and to their duties under the legislation which in recent years has caused the raising of so many questions relating to the extent and duration of physical incapacity in connexion with the compensation of workmen. A new principle seems here to have been introduced in the trial of scientific questions in cases which are of frequent occurrence, but which, considered in relation to the issue at stake, may be of minor significance. The correct appraisement of the incapacity of a workman earning 25s. a week is important, but so are the reality and extent of the injuries sustained in a railway accident by a wealthier man who claims thousands of pounds. And still more urgent are the calls for justice in the case of the alleged insanity of a testator who has sought to dispose of millions by will, or in that of a man whose life hangs upon the question whether or not he wilfully murdered his fellow man. Surely there is greater need in these last instances of some form of medical assessors.

The English and Scottish Courts and the Plea of Insanity.

The highly interesting and, indeed, exhaustive article of Professor John Glaister which we publish this week sets out the practice of the courts of Scotland with regard to the raising of the plea of insanity at the trial of charges of nurder or of other crimes, and compares it with the pro-cedure prevailing in England. In particular he calls atten-tion to recent cases in Scotland, where the events described might be possible as a matter of law in England, though they would be contrary to established practice. The raising of the question of the sanity of the prisoner as affecting his capacity to plead is usually reserved in England for those cases where the state of the prisoner's mind is believed to be such that there is a doubt whether his trial might not be regarded as an act of cruel injustice. Professor Glaister's Case 3 (p. 1430), fully set out by the writer, should be of considerable interest to barristers practising in English criminal courts, and not already acquainted with it; as should Case 4, not only with regard to the relative attitudes of prosecution and defence towards the question of insanity, but also in respect of the period in the proceedings at which the decision of the court with relation to the prisoner's capacity to plead was allowed to be still under discussion. English lawvers will probably be of opinion that there is a difference between the courts of Scotland and of England in the judicial attitude towards the defence of insanity. The course pursued by Lord Young in Case 1 was no doubt astonishing to

those engaged in it, but the general effect produced is that of a fuller appreciation on the part of Scotch judges of the possibility of a man who commits a crime with ingenuity, with cool calculation, and with premeditation being in such a mental condition as not to be legally responsible for it. This is a possibility, and in Scotland a position is more readily adopted consistent with this view by prosecuting counsel. In England a person whose insanity is not of a marked and apparent character is usually tried, the possible verdicts being guilty, not guilty, or guilty but insane at the time of the commission of the offence; sanity is presumed until the contrary is proved by those responsible for his defence, and criminal trials will be recalled which have been tried out even when the power of the prisoner to follow the proceedings with any effect and to instruct his counsel rationally must have seemed very doubtful to all concerned. The complete trial of Richard Arthur Prince for the murder of Terriss, the famous actor, may be cited as an instance where a verdict of insanity was a foregone conclusion. It may be added that the raising of the issue of fitness to plead in the well-known case (No. 3) cited by Professor Glaister, where the actual committing by the accused of the acts alleged was open to serious question, and in spite of resistance upon the part of defending counsel, is difficult to understand or to justify, and only less strange than the allowing this issue to be decided after trying out the case without a conclusion being arrived at as to whether he killed the deceased or not. From a medical point of view the jury may be said to have had left to it the scientific question which it was least competent to answer, and to have been allowed to return no verdict as to the one matter on which it was best qualified to deliver one, although it had before it all the evidence obtainable on the subject.

Sale of Medicines.

The case of the Pharmaceutical Society v. Mercer, before Mr. Justice Darling and Mr. Justice Bucknill on Oct 28th, was an appeal by the defendant from a decision of the county court judge at St. Helens. The plaintiffs sued the defendant to recover a penalty under Section 12 of the Pharmacy Act, 1852, which makes it unlawful for a person who is not registered to use the title of pharmaceutical chemist or pharmaceutist or to assume, use, or exhibit any name, title, or sign implying that he is registered under the Act or that he is a member of the Pharmaceutical Society. The defendant, who was not registered under the Act, sold medicines at a shop on which, and on the medicines sold by him, was the defendant's name, followed by the words "The Pharmacy." The county court The county court judge found that the defendant had contravened Section 12 by the use of the words "The Pharmacy" in the circumstances stated, and he accordingly imposed a penalty. defendant appealed. The court allowed the appeal, being of opinion that the words "The Pharmacy" were descriptive of the place where the defendant carried on business, and were not descriptive of the defendant himself, and that they did not imply that the defendant was registered under the Act or was a member of the Pharmaceutical Society.

" Dr." Bodie.

After a prolonged trial "Dr." Bodie has been adjudged by a jury to have been guilty of fraudulent misrepresentation, and has been ordered to repay the sum of £1000 which he obtained from a young man who desired to be initiated into the mystery of his outrageous performances. We congratulate the plaintiff, Mr. Irving, on his success and on its resulting in an exposure of Bodie and Bodie's methods.

ROYAL SOCIETY OF ARTS.—The meetings of the Royal Society of Arts will recommence on Wednesday, Nov. 17th. at 8 P.M., when Sir William White, Vice-President and Chairman of the Council, will deliver an address entitled "An Imperial Navy." The subject of the subsequent Wednesday evening discourses before Christmas will be: "Photo-telegraphy." "Resilient Wheels for Vehicles," "Destruction of Plumage Birds," and "Diamond Fields of Brazil." Four Cantor lectures on "Aeronautics" will be delivered at 8 P.M. on Nov. 29th and Dec. 6th, 13th, and 20th. A meeting of the Colonial Section will be held on Nov. 30th, and of the Indian Section on Dec. 9th.

Public Bealth.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On an Outbreak of Enterio Fever in the Urban District of North Ormesby, by Dr. R. W. JOHNSTONE. 1-This report deals with the incidence and causation of enteric fever in North Ormesby in 1908. This district, with a population of about 15,000, is practically a continuation of the town of Middlesbrough. For many years past there has been an undue prevalence of enteric fever in North Ormesby, and last year 63 cases were notified. Of these, 17 were under the age of 10 years; 31 were males and 32 were females. The disease was prevalent through August, September, October, and the early part of November, after which there was a rapid drop in the occurrence of cases. The invaded houses. 49 in number, were, with three exceptions, situated in the north-eastern half of the town, and the majority were found in a particular group of streets. The sewers of this half of North Ormesby form a system distinct from that of the south-western half. In the district generally the sewers have insufficient gradients and are badly laid, while house-drains are often faulty and become choked. The opportunities of sewer air escaping in or about dwellings were increased by the circumstance that in 1908 the sewers were unventilated. A suggestion was made that sewer gas which developed in certain tanks at the outfall works had been able to pass back through the sewers to the north-eastern part of the town, but had been shut off from the rest of the district by a trap accidentally formed by the faulty construction of the main sewer which serves the southwestern portion. The tanks in question, however, were not air tight, and Dr. Johnstone considers that the back pressure which would be necessary could hardly have taken place. The district is served by midden privies and pail closets in about equal numbers Most of the invaded houses had midden privies. The grouping of the invaded houses could to some extent be accounted for on the probable assumption that middens in the area specially affected became infected early in the outbreak, and that infection was caused by these middens through the agency of flies or in other ways. Stable manure is well known to be a favouritebreeding place for flies, and Dr. Johnstone notes that there was a stable in the centre of the region specially affected. Flies were reported to be exceptionally abundant in North Ormesby during the autumn of last year. Dr. Johnstone also reviews, mainly with negative conclusions, the influence of water and milk-supplies, and also of certain foods, shell-fish, fried fish, ice-cream, and uncooked vegetables. In regard to the latter foods he adopted the useful plan of comparing the results of the inquiries which had been made as to the diet of the persons attacked with the facts obtained in course of a census taken in two or three typical streets. For this census inquiries were made at 174 houses and of 827 persons, so as to obtain a rough idea of the normal frequency with which the several articles in question are consumed by the population. No very marked discrepancy appeared between the information obtained as to the persons attacked and that which was provided by the census, except in the case of shell-fish. Only 60 out of the 827 persons said that they had +aten shell fish of one sort or another during the summer of 1908, whereas out of 62 cases of enteric fever in which inquiry was made 16 were reported to have eaten shell-fish within a period of from 5 to 21 days before the onset of the enteric tever Mussels and periwinkles which are hawked in North Ormesby are usually obtained from the Tees below Middlesbrough, where the river is badly contaminated by sewage.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Glasgow.—There is very material disparity between the population of Glasgow as estimated (859,715) by the Registrar-General on the one hand and by the medical officer of health (801,250) on the other, and Dr. A. K. Chalmers makes use of the circumstance to emphasise the necessity for a quinquennial census, since under existing conditions the Registrar-General credits Glasgow with an

¹ Public Health Reports, New Series, No. 17. London: Wyman and Sons, Fetter-lane; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. Price 4d.

increase and the medical officer of health with a decrease of population, and, as a result, all the rates for the year under notice must be accepted as provisional only. The infantile death-rate of this city for 1908 was 136 per 1000 births, a rate which was materially exceeded by Dundee, Manchester, and Birmingham. During the years 1907-08 an inquiry into the physical condition of Glasgow children was conducted by Dr. A. S. M. MacGregor among the patients admitted into the Belvidere Fever Hospital, the object of the investigation being to obtain a record of the height and weight of children under school age, and to ascertain the child's capacity for immediate improvement under better conditions than those to which it had been accustomed. The inquiry further aimed at obtaining information as to the physique of the rachitic child and its relation to housing conditions and as to the physique of infants in relation to their susceptibility to infectious disease. Some of the results of this inquiry have already appeared in our columns, but we may briefly deal here with the rachitic conditions found. Of 1357 children between the ages of 2 and 10 years rickets were discovered in 31 per cent. of the males and 26.7 per cent. of the females, while of 329 children aged from 6 months to 2 years the incidence upon the combined sexes was 42.5 per cent. In the matter of the possible influences of parentage in production of rickets, an instructive table is furnished in Dr. Chalmers's report, showing that in cases where the parents and child were Glasgow born the incidence (44.4 per cent.) of rickets was greater than in cases where the Glasgow native was less and less concerned. For example, where the parents and children were born out of Glasgow the percentage incidence of rickets was only 25.4 per cent. Of the cases of enteric fever occurring in Glasgow during 1908 87.7 per cent. were treated in hospital and the fatality-rate was 12.1 per cent. The death-rate from this disease in Glasgow has steadily decreased since 1881-90, when it was 0.230 per 1000. There was a "return" case of enteric fever during 1908 in connexion with a patient who had been recently discharged from hospital and in whose urine the pathogenic bacteria were discovered, and as recently as July, 1909, the organisms were still recoverable from the urine. Of typhus fevers there were 13 cases with 1 death. There is a capital chart in the report showing the monthly variations of scarlet fever in each year from 1898 to 1908. In 1898 the disease was ascending and reached its maximum in 1899, there being after that a gradual descent until 1905, when a rise again commenced. The death-rate from pulmonary tuberculosis has undergone steady diminution since the quinquennium 1860-64, when it amounted to 4094 per 1,000,000, the rate having reached in 1908 the low figure of 1417 per 1,000,000. Upon the subject of pulmonary tuberculosis Dr. Chalmers contributes a special memorandum in which he deals with such interesting subjects as the segregation of early or advanced cases, and he comes to the conclusion that perhaps the greatest good would accrue from a training for one month in a sanatorium of relatively early cases of the malady, the object of such training being to teach the patients how to regulate their lives with best prospects to their own health and least risks to those with whom they are brought into contact. Dr. Chalmers points out that if the patient learns to control both his sputum and the droplets coughed up "he will accomplish so far as direct prevention of infection is concerned all that isolation in hospital may accomplish. He may, in effect, and by his own action, isolate himself in a way quite unknown in connexion with the other infectious Dr. Chalmers has advised, and the corporation has accepted, a system of compulsory notification of cases of pulmonary tuberculosis and it has also accepted his further recommendations to provide five additional tuberculosis dispensaries in addition to the one which already exists.² There is to be a nurse in connexion with each of these institutions and their visits to the homes of the patients are to be supervised by a medical officer specially appointed for the purpose. In this way Dr. Chalmers hopes to improve the circumstances under which the patients and the people in the invaded houses live and thus to raise the condition of the contacts above what has been termed the pre-tuberculous stage. He lays great stress upon the importance of resistance as a factor in the prevention of phthisis, and as regards the part which may be played in causation of tuberculosis by the human or bovine sources he observes: "Whatever subsequent inquiry

may establish regarding the part played by either in distributing infection or regarding the precise channels by which it reaches the child, there does not seem much ground for anticipating that it will substantially alter the view which is so widely held at present, that receptivity or susceptibility to infection is probably, even more than the presence of the bacillus, the dominating factor in determining the development of the disease." He estimates the cost of a sanatorium with 100 beds, which would train 1200 patients annually in sputum control and the like, at £8000, apart from interest on the capital sum expended and the repayment of such capital; and he observes that in view of the many insanitary portions of Glasgow which still require to be dealt with it may be suggested that the expenditure of £8000 annually in removing foci of disease could not fail eventually to be productive of permanent advantages, not only with regard to consumption, but to disease generally.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8350 births and 4180 deaths were registered during the week ending Nov. 6th. The annual rate of mortality in these towns, which had been equal to 12.0 per 1000 in each of the two preceding weeks, rose to 13.3 in the week under notice, and was higher than in any week since the middle of May. During the first five weeks of the current quarter the annual death-rate in these towns averaged 12.5 per 1000, and in London during the same period the rate did not exceed 12.2 per 1000. The lowest annual rates of mortality recorded in the 76 towns last week were 5.2 in Leyton, 5.8 in Barrow-in-Furness, 6.8 in Willesden, and 7.3 in Kast Ham; the rates in the other towns ranged upwards, however, to 18.6 in Grimsby, 19.4 in Bury, 20.8 in Middlesbrough, and 22 · 7 in Hanley. In London the recorded death-rate last week increased to 13.4 per 1000. The 4180 deaths registered in the 76 towns last week exceeded by 394 the low number in the previous week, and included 283 which were referred to the principal epidemic diseases, against numbers declining steadily in the ten preceding weeks from 849 to 293; of these 283 deaths, 111 resulted from diarrhœa, 43 from measles, 42 from diphtheria, 36 from scarlet fever, 31 from whooping-cough, 19 from "fever" (principally enteric), and one from small-pox. The 283 deaths from these epidemic diseases last week were equal to an annual rate of 0.9 per 1000, corresponding with the low rate from these diseases in the previous week. No death from any of these epidemic diseases was registered last week in Croydon, East Ham, Walthamstow, Leyton, or in 11 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·3 in Hull, 2·6 in Walsall, 2·9 in Wallasey, and 9·1 in Hanley. The deaths attributed to diarrhoea in 9.1 in Hanley. The deaths attributed to diarrncea in the 76 towns, which had declined in the 10 preceding weeks from 675 to 110, were 111 last week; the highest death-rates from this cause in the 76 towns last week were 1.3 in Preston, 1.5 in Wallasey, 2.1 in Walsall, and 3.0 in Hanley. The fatal cases of measles showed a further increase to 43 last week, and exceeded the number in any week since the middle of August; they caused annual rates equal to 1.4 in Ipswich, 1.6 in Hornsey, and 4.5 in Hanley. The deaths from diphtheria, which had been 46 and 57 in the two previous weeks, declined to 42 last week, and included 15 in London and its suburban districts, 4 in Manchester and Salford, 4 in Hull, 3 in Portsmouth, 3 in Birmingham and King's Norton, and 2 each in Sunderland and South Shields. The 36 fatal cases of scarlet fever showed an increase of 6 upon the number in the previous week; 6 occurred in Manchester, 4 in Birmingham, and 3 in Liverpool. The 31 deaths from whooping-cough were fewer by 11 than the number in the previous week, but included 16 in London and its suburban districts. The 19 deaths referred to "fever" showed a slight increase, and included 2 each in Portsmouth, Hanley, and Bolton. The fatal case of small-pox was registered in Swansea. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had been 2810, 2799, and 2743 on the three preceding Saturdays, had further declined to 2696 on Saturday last; 336 new cases of this disease were admitted to these hospitals during last week, against 371,

THE LANCET, August 14th, 1909, p. 500.
 See also THE LANCET, Nov. 6th, 1909, p. 1364.

345, and 284 in the three preceding weeks. The Metropolitan Asylums Hospitals contained 3 small-pox patients on Saturday last. Of the 1246 deaths registered in London last week, 230 were referred to pneumonia and other diseases of the respiratory system, against 167, 174, and 193 in the three preceding weeks; these 230 deaths were, however, 43 below the corrected average number in the corresponding week of the five years 1904-08. The causes of 26, or 0.6 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered last week were duly certified in London, Manchester, Sheffield, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 55 smaller towns; the 26 uncertified causes of death in the 76 towns last week included 9 in Liverpool, and 2 each in Leeds, South Shields, Gateshead, and Burton-on-Trent.

HRALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 790 births and 547 deaths were registered during the week ending Nov. 6th. The annual rate of mortality in these towns, which had been equal to 13.1 and 12.9 per 1000 in the two preceding weeks, rose to 15.3 in the week under notice. During the first five weeks of the current quarter the annual death-rate in these Scotch towns averaged 13.2 per 1000, and exceeded by 0.7 the mean rate during the same period in the 76 large English towns. The annual death-rates last week in these Scotch towns ranged from 8.5 and 11.6 in Perth and Leith, to 15.9 in Greenock and 18.2 in Glasgow. The 547 deaths from all causes in the eight towns last week showed an increase of 85 upon the number in the previous week, and included 67 which were referred to the principal epidemic diseases, against 54 and 34 in the two preceding weeks. These 67 deaths were equal to an annual rate of 1.9 per 1000; the mean rate from the same diseases last week in the 76 largest English towns did not exceed 0.9 per 1000. The 67 deaths from these diseases in the Scotch towns last week included 24 from measles, 13 from diphtheria, 13 from diarrhosa, 11 from whooping-cough, 4 from scarlet fever, and 2 from "fever," but not one from small-pox. The 24 fatal cases of measles showed a marked increase upon recent weekly numbers, and included 18 in Glasgow and 5 in Edinburgh. The 13 deaths from diphtheria also showed a considerable increase; 9 were returned in Glasgow and 2 in Leith. The 13 deaths attributed to diarrhosa exceeded the number in the previous week by 3, and included 7 in Glasgow, 4 in Dundee, and 2 in Paisley. The 11 fatal cases of whooping-cough also showed an increase; 6 occurred in Glasgow, and 3 in Greenock. Three of the 4 deaths from scarlet fever were recorded in Glasgow; and of the 2 referred to "fever" one each occurred in Glasgow and Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 84 and 68 in the two preceding weeks, rose last week to 108, but were 8 below the number in the corresponding week of last year. The causes of 12, or 2 · 2 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.6 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,142,308 persons, 608 births and 381 deaths were registered during the week ending Nov. 6th. The mean annual rate of mortality in these towns, which had been equal to 14.8 and 16.4 per 1000 in the two preceding weeks, further rose to 17.4 in the week under notice. During the first five weeks of the current quarter the annual death-rate in these Irish towns averaged 15.8 per 1000, whereas the mean death-rate during the same period did not exceed 12.5 in the 76 largest English towns, and 13.2 in the eight principal Scotch towns. The annual death-rate last week was equal to 18.6 in Dublin, 15.6 in Belfast, 22.6 in Cork, 15.7 in Londonderry, and 13.7 in Limerick; the mean rate in the 16 smallest Irish town districts last week was equal to 19.5 per 1000. The 381 deaths from all causes in the 22 town districts last week showed a further increase of 22 upon the numbers in the two previous weeks, and included 21 which were referred to the principal epidemic diseases, against 22 and Price, from the 1st Forfarshire Royal Garrison Artillery

26 in the two preceding weeks; these 21 deaths were equal to an annual rate of $1\cdot 0$ per 1000; in the 76 largest English towns the rate last week from the same diseases did not exceed 0.9 per 1000. The 21 deaths from these epidemic diseases in the Irish towns last week included 12 from diarrhea, 5 from whooping-cough, and 4 from enteric fever, but not one from measles, scarlet fever, diphtheria, or small-pox. The 12 deaths attributed to diarrhœa corresponded with the number in each of the two preceding weeks, and included 4 in Belfast, 3 in Sligo, and 2 both in Dublin and in Cork. Four of the 5 fatal cases of whooping-cough occurred in Belfast; and of the 4 deaths referred to enteric fever, 2 were returned in Cork and 1 both in Dublin and in Drogheda. The deaths resulting in the 22 towns from pneumonia and other diseases of the respiratory system, which had been 50 and 60 in the two preceding weeks, further rose to 86 in the week under notice. The causes of 13, or 3.4 per cent., of the deaths in these Irish towns last week were not certified by a registered medical practitioner or by a coroner; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.6 per cent, and in the eight Scotch towns the proportion was 2.2 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: -Surgeons: A. R. Schofield to Hong-Kong Hospital; J. E. Johnston to the Ringdove; C. A. G. Phipps to the Pembroke for R. N. Barracks: T. W. Myles to the Hyacinth; W. F. Archibald to Chatham Hospital; and A. McCloy to the Pembroke for R.N. Barracks.

ROYAL ARMY MEDICAL CORPS SCHOOL OF INSTRUCTION.

Lieutenant-Colonel George D. Hunter, D.S.O., R.A.M.C., to be Commandant, vice Lieutenant-Colonel C. E. Nichol, D.S.O. (dated Nov. 1st, 1909).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated Oct. 28th, 1909) :- Brian Watts, Henry G. Martin, Frederick F. Carroll, John D. G. Macpherson, William P. Gwynn, Standish de C. O'Grady, Augustus H. O. Young, Ernest A. Bourke, Montagu M. Lowsley, Gerald B. Carter, and Norman H. Ross.
Captain Arthur C. H. Gray, from the Seconded List, is

restored to the establishment (dated Oct. 25th, 1909).
Surgeon-General W. W. Kenny, at present serving as
Principal Medical Officer in South Africa, has been appointed Principal Medical Officer of the Northern Command. Colonel O. E. P. Lloyd, V.C., Principal Medical Officer, 7th (Meerut) Division, India, has been appointed Principal Medical Officer, South Africa. Lieutenant-Colonel F. J. Jencken has been appointed to charge of the Royal Victoria Hospital, Netley, and Lieutenant-Colonel A. Kennedy to the charge of D Block of the same institution. Lieutenant-Colonel R. J. C. Cottell has been appointed Physician and Surgeon to the Royal Hospital, Chelsea, and Major F. Kiddle Deputy-Surgeon.

Major T. W. Gibbard has been appointed Lecturer in
Syphilology at the Royal Army Medical College, Millbank, S.W., and to charge of the Military Hospital, Rochester-row.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions:—Captains to be Majors (dated July 28th, 1909): John Walter Forbes Rait, Eugene John O'Meara, Spencer Hunt, and Henry Albert John Gidney. Lieutenants to be Captains (dated Sept. 1st, 1909): John Taylor, Alexander Dron Stewart, Claude Harold Cross, Robert Alexander Chambers, John Morison, Samuel George Steele Haughton, Francis William Cragg, Andrew Smith Leslie, Herbert Bodley Scott, and George McGregor Millar.

Captain G. W. Maconachie has been appointed to the substantive medical charge of the 73rd Carnatic Infantry vice Captain W. C. Hamilton. The services of Captain Dulton have been temporarily placed at the disposal of the Bengal Government. Captain Powell, Officiating Super-intendent of Midapore Jails, is granted six months' leave. Major Smith is appointed a Civil Surgeon at Quetta.

TERRITORIAL FORCE.

(Volunteers), to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908).

Royal Army Medical Corps.

F South Wales Mounted Brigade Field Ambulance: Captain John Griffiths, from the List of Officers attached to units other than Medical Units, to be Captain (dated August 10th, 1909).

3rd Highland Field Ambulance: Lieutenant Sidney W. Smith resigns his commission (dated June 15th, 1909). Henry James Gorrie to be Lieutenant (dated Sept. 10th, 1909)

2nd West Lancashire Field Ambulance: George Charles Edward Simpson to be Lieutenant (dated Oct. 4th, 1909).

2nd Lowland Field Ambulance: Lieutenant James A. H. Aitken to be Captain (dated Oct. 28th, 1909).

- 2nd North Midland Field Ambulance: Captain Montague S. W. Gunning resigns his commission (dated Sept. 1st, 1909).

2nd Welsh Field Ambulance: Owen Lewellin Rhys to be

Lieutenant (dated Sept. 25th, 1909).

1st Scottish General Hospital: Captain William A. I.
Fortescue resigns his commission (dated Oct. 9th, 1909).

Attached to Units other than Medical Units. - Lieutenant Harry Armitage Robinson to be Captain (dated Sept. 28th, 1909).

The transfer of Surgeon-Lieutenant Lloyd Turton Price from the 1st Forfarshire Royal Garrison Artillery (Volunteers), which was announced in the London Gazette of Nov. 6th, 1908, is cancelled.

Correspondence.

"Audi alteram partem."

THE LATE DR. JOHN HERBERT WELLS. To the Editor of THE LANCET.

SIR,—The death of Dr. John Herbert Wells last month at the early age of 30 years adds another name to the list of those who have lost their lives in the cause of scientific medical research.

After distinguishing himself in original research, Dr. Wells joined the department of therapeutic inoculation at St. Mary's Hospital, where this branch of treatment was advanced materially by his labours. In February, 1908, Dr. Wells undertook pioneer investigation of the treatment of glanders, and in the course of laboratory work which resulted in saving the life of the patient from this, till then, hopeless disease, contracted infection himself, and died after 18 months of suffering on Oct. 16th, 1909, leaving a widow and two small children almost totally unprovided for.

Throughout his long illness Dr. Wells's constant hope was to return to the work in the cause of which he had suffered so severely. He was held in high esteem by the members of his profession, and his thoroughness and personality won him many friends, as the obituary notice in THE LANGET of Oct. 23rd abundantly testified. His life was rich with promise and was laid down with manly fortitude as the penalty of his scientific zeal.

A committee has been formed, consisting of the Right Hon. A. J. Balfour, M.P., the Earl of Dalhousie, Lord Justice Fletcher Moulton, Sir Almroth Wright, M.D., F.R.S., Mr. H. A. Harben (late chairman of St. Mary's Hospital), Mr. Julian G. Lousada, Mr. Edmund Arthur Smith (of the Stock Exchange), and Dr. W. H. Willcox; and they now appeal to the public for donations to a fund to be held in trust for Dr. Wells's widow and children.

The committee (on whose behalf we write) feel strongly that in such a case as this, where a man has laid down his life in trying to relieve the sufferings of mankind, it is eminently fitting that some recognition should be made of his work, and they have full confidence that the public will make a ready response to their appeal.

All contributions sent to the Honorary Secretaries and Treasurers of the fund at 16. Old Broad-street, London, E.C., will be gratefully acknowledged.

Yours faithfully, DALHOUSIE. DALHOUSIE,

Julian G. Lousada.

Joint Honorary Secretaries and Treasurers. 16, Old Broad-street, London, E.C., Nov. 11th, 1909.

* * We are able to announce that the colleagues of the late Dr. J. H. Wells on the staff of the department of therapeutic inoculation at St. Mary's Hospital are making an independent subscription which will be added to the fund later. We shall be happy to receive and acknowledge subscriptions to this fund. -ED. L.

THE STATUS LYMPHATICUS.

To the Editor of THE LANCET.

SIR,—The prominence which has been given in the press during the last three years to the subject of deaths under chloroform has produced in the public mind a feeling of considerable uneasiness, and it is surprising to remember in this connexion how small is the progress we are making towards understanding the lymphatic state. At the risk of an accusation of prematurity, but in the hope of stimulating discussion, or at least some publication of experiences, I venture to submit a few words on the subject, suggesting the line of thought which has been forced upon me by a study of the literature available and by a retrospective examination of my clinical records.

Definition.—Status lymphaticus is a name given to a combination of conditions found post mortem in the bodies of certain young persons who have died suddenly and "unaccountably," or from "inadequate" causes, of which the inhalation of chloroform vapour is here assumed to be the most important. Evidence has frequently been given that such patients presented during life no disease or peculiarity beyond the presence of "adenoids," for the cure of which they may have been undergoing operation at the moment of death.

The Vienna School recognised the importance of this condition as a factor in causing danger in anæsthesia many years before the rest of Europe, or America, began to pay attention to it (J. Ewing). The researches tend to show that status lymphaticus cannot be entirely rejected as a pathological entity, although it, as a picture or idea, is open to the criticisms which have demolished the old pathological "diatheses."

Post-mortem findings.—There have usually been some or all of the following in order of frequency: (1) enlargement of a few, or many, groups of lymphatic glands and of the lymph follicles of the intestinal mucosa; (2) enlargement of the spleen; (3) persistence of the thymus gland in a functional condition; (4) hyperplasia of the red bone marrow; (5) enlargement of the thyroid body; (6) in infants, signs of rickets; (7) in adolescents, hypoplasia of the heart and narrowing of the aorta.

Clinical realities. - Paltauf's theory, supported by Warthin, that the condition is a "lymphotoxemia," with com-pensatory enlargement of the thymus, receives support from a comparison of the three types of patient (now to be described), who may, and not infrequently do, exhibit untoward symptoms when under the influence of chloroform. It is noteworthy that the condition in all three types occurs in young or early mature persons.

1. Young persons, chiefly female, suffering from chronic anæmia and constipation—both points which may be easily overlooked or under-estimated by the anæsthetist in his preliminary examination. When the tissues of a patient are already saturated with one poison, the addition of a When the tissues of a patient very small dose of another may be fatal (and this applies not only to this type of case, but also to the two other types which follow). The danger of giving morphine to a nephritic patient is an example. In cases of pronounced copric anæmia the tissues are in a low state of vitality and are liable to outright destruction by a very small dose of chloroform. The heart's action is always weak, and often slow and irregular, so that pulse and respiration seem to fail simultaneously when danger appears under chloroform; the fact that artificial respiration applied without delay is usually successful in restoring the patient proves that in these cases the respiratory centre is more deeply poisoned than the heart muscle. Pure chloroform should never, when possibly avoidable, be given to such patients, and the greatest vigilance and care are necessary when administering mixtures.

2. Young persons, more often males, often largely and loosely built, who show on examination: (a) some enlargement of the thyroid and fulness of the episternal notch; (b) a palpable or percussible enlargement of the spleen: (c) an abnormally slow and inexcitable pulse, and this in spite of the fact that the patient may be in a miserably anxious and apprehensive state on account of the imminence of and apprenensive state on account or the imminence of the operation. With this there may be, but not constantly, dilatation of the heart. The face is anæmic and rather vacuous, and the pallor may be masked by some degree of cyanosis. These are the cases, in my opinion, to which the name "Status Lymphaticus" should be restricted. The behaviour of these patients under anæsthetics other than chlamfurm is interesting and angular gestive collateral. For instance, nitrous oxide is the most frequently used of all anæsthetics in this country, and the users of this gas can, with little trouble, supply a mass of clinical material of the greatest value. In my experience (15 cases under all anæsthetics) the patient who is only slightly "lymphatic," presenting no signs beyond some lividity of the hands and slight sluggishness of the pulse, requires much more than the normal volume (8 to 12 gallons) of N₂O to "get him over," though, once unconscious, the anaesthesia is sometimes profound and lasting. Such a patient may require as much as 20 gallons of $N_2\tilde{O}$, especially in warm damp weather. Again, a patient who presents all the signs of lymphatism in a well marked degree may be totally insusceptible to the narcotising properties of N₂O. He may inhale 30 or 40 gallons without admixture of air for even three minutes and show no result whatever beyond slight dizziness and profuse perspiration. These patients, I believe, always show some abnormality of reaction to nitrous oxide, they may show danger signs under chloroformether mixtures, and under pure chloroform they almost certainly nill give trouble. Their reaction to ether does not seem to differ greatly, if at all, from the normal, though Heusler reports a death after ether and much loss of blood.

3. Young parturient numen.—No clinical observation has ever been so mistaken as that which stated that pregnancy conferred immunity from the poisonous effects of chloroform. There are here more factors than one tending to produce too easily an overdose of chloroform vapour (the favourite anæsthetic under these circumstances).

There is the diminished "vital capacity" due to encroachment upon the diaphragmatic portion of the thorax, there is the increased carrying capacity of the red blood corpuscles, there is the physical exhaustion produced by prolonged pain and muscular activity, and, hand in hand with this, there is toxemia from over-metabolism plus foetal metabolism. It is thus not surprising that artificial respiration is fairly commonly called for, and nothing else is necessary, because the heart is stronger than normal, and it is respiration which undoubtedly fails first.

It is only because the subject is one of general interest at the present time that I do not reserve the matter for the collection of further material.

I am, Sir, yours faithfully,
DONALD J. MUNRO, B.S., M.B. Lond.,
Anæsthetist to the Metropolitan Ear, &c., Hospital. Welbeck-street, W., Nov. 6th, 1909.

LUNG PUNCTURE.

To the Editor of THE LANCET.

SIR, -In the interesting annotation on this subject in your last issue it is stated that "the only conditions which suggest themselves as disadvantages are the possibility of infection of the healthy pleura or of the needle track in septic cases, and the occurrence of hæmorrhage from wounding a vessel or an aneurysm of the pulmonary artery." There is yet another danger to which attention has been called by Dr. George Oliver, Dr. A. E. Russell, and myself, and to which

references will be found in a paper by me in Vol. V. of the Reports of the Society for the Study of Disease in Children, 1905, p. 118. In these cases the patient, who is often in a cachectic condition, immediately after exploratory puncture of the pleura becomes cyanotic and dies. Brouardel has recorded a case in which this occurred when an attempt was made to aspirate a hydatid cyst of the lung. The needle in this case only entered the lung and did not touch the cyst. In a case recorded by Dr. George Carpenter death was due to suffocation by hæmorrhage, but in the others no hæmorrhage was proved to have occurred, and Dr. Russell has suggested that the phenomenon is a reflex inhibition of the cardiac and respiratory centres due to irritation of the afferent fibres of the vagus.

Though rare, this occurrence constitutes a real danger which ought not to be overlooked, especially as the class of case in which exploratory puncture of the lung would be likely to be done is exactly that class in which the percentage of fatal accidents might be expected to be highest.

I am, Sir, yours faithfully, J. M. Fortescue-Brickdale, M.A., M.D. Oxon. Clifton, Bristol, Nov. 9th, 1909.

To the Editor of THE LANCET.

SIR,-I was much interested in reading Dr. Horder's paper on "Lung Puncture, a New Application of Clinical Pathology" in your issue of Nov. 6th. As he stated he could find no reference to such an application of clinical pathology, may I draw his attention to some remarks by Dr. C. J. Macalister on "The Treatment of Chronic Pneumonia by Puncture" and Dr. Blair Bell's comments thereon at a meeting of the Liverpool Medical Institution, reported in the British Medical Journal, Nov. 3rd, 1900? In a subsequent issue I wrote to the effect that I had used that treatment in 1887 and 1889, as reported in a paper entitled "A New Method of Bleeding in Some Cases of Pulmonary Congestion, which was published in THE LANCET in 1891.

Cambridge.

I am, Sir. yours faithfully,
J. Christian Simpson, M.D. Edin.

APPENDICITIS WITH HÆMATURIA.

To the Editor of THE LANCET.

SIR,—Recently I operated on a little boy, aged 31 years, for acute appendicitis, with a large abscess. Two weeks after the operation he passed large quantities of blood from the bladder. On analysis there was nothing to be seen but blood and oxalate of lime crystals. The hæmorrhage continued off and on for five weeks. The urine now is perfectly normal and has been so for three weeks. Is this possibly a similar case to that recorded by Mr. P. H. V. Hammersley. and reported in your annotation of Nov. 6th?

I am, Sir, yours faithfully,

WM. BURROUGH COSENS. Dorchester, Nov. 6th, 1909.

THE INFLUENCE OF DIET ON THE THYROID GLAND.

To the Editor of THE LANCET.

SIR,—With your permission I should like to comment on a statement in Dr. Chalmers Watson's interesting letter in THE LANCET of last week. He says, "There are conditionse.g., gout-in which the administration of a diet which contains little protein is of special value this favourable result is in an important degree attained through the influence of that diet on the thyroid gland."

While admitting without question that the form of diet mentioned may produce favourable results, I must confesswith the greatest respect to Dr. Chalmers Watson's admirable researches on the subject-to some scepticism as to the result being due to the influence of the diet on the thyroid gland. If this were so, then a diet consisting entirely, or almost entirely, of protein would, if I understand Dr. Watson rightly, have a converse effect upon the gland and so aggravate the condition, but this is not so. For instance, Dr. Luff has frequently drawn attention to the value of an exclusive meat diet in certain cases of gout, and my own experience has been that the majority of cases may be benefited by this regimen.

Probably Dr. Chalmers Watson may be able to explain the paradox. The only explanation I have to offer as to why a diet approximating to a purin-free diet, and a converse form of diet such as the exclusive meat diet, are each capable of producing good results in gout, is that both, if carefully regulated to the digestive capacity of the individual, tend to eliminate—as may be proved by periodical examination of the urine and fæces—the chief causative factor, viz., autotoxæmia.

I am, Sir, yours faithfully,

Wimpole-street, W., Nov. 8th, 1909.

ERNEST YOUNG.

ENTERICIN IN THE TREATMENT OF ENTERIC FEVER.

To the Editor of THE LANCET.

SIR,—A large number of clinicians will be interested in your annotation of last week describing the results obtained by Mr. John Maberly of Cape Colony with a drug prepared from Monsonia biflora in the treatment of enteric fever, and it is to be hoped that this preparation will be given a fair trial in this country. At the same time I think a protest is needed against the name "entericin" which has been given to its active principle. The analogy between that name and such words as "tuberoulin" and "mallein" is so obvious that to many the word "entericin" will connote a vaccine made from the typhoid bacillus, and not a vegetable compound. Surely "monsonin" would be a name in strict accordance with pharmacological precedent, and would obviate the confusion likely to arise from the present title. Uniformity in scientific nomenclature is always desirable.

I am, Sir, yours faithfully,

Nov. 9th, 1909.

VERBUM SAP.

MALARIAL FEVERS IN INDIA.

THE CONFERENCE APPOINTED BY THE GOVERNMENT OF INDIA.

(FROM A SPECIAL CORRESPONDENT.)

The Opening Address by H. E. The Viceroy.

THE conference appointed by the Government of India on the prevalence and prevention of malarial fevers in India held its first meeting at Viceregal Lodge, Simla, on Oct. 12th. There were present, besides the members and delegates representing the various presidencies already communicated to you, Sir Louis Dane (Lieutenant-Governor of the Punjab), Sir Herbert Risley (officiating home member of the Viceroy's Council), and Sir Harold Stuart (Home Secretary). The meeting was opened by His Excellency Lord Minto, Viceroy and Governor-General of India, who, after welcoming the delegates, gave a most interesting address in which he impressed on the conference the vast importance of the matter they had been called together to discuss. He referred to the fact that malarial fevers ordinarily claim 1,000,000 deaths in India annually, and in exceptional seasons they have risen to 2,000,000. There were also the cases of those who contract the disease but do not die, and the ratio of these has been placed at 133 cases of fever to 1 death. It was appalling to think of the suffering and economic loss that such conditions imply, not only direct and immediate loss by the death and sickness of adults, but potential loss in the case of children. The chief problem before the conference would be to discover by what means this widespread suffering could be preventible. His Excellency next passed in review the work of the French army surgeon Laveran in 1880, the brilliant suggestions of Sir Patrick Manson in 1894, and the discovery by Major Ronald Ross of the Indian Medical Service in 1897, all connected with the life-history of the malarial parasites. The question of the possibility to exterminate a particular kind of mosquito from malarious localities confronts us, he said, with another problem. The answer, Lord Minto ventured to think, rested rather with the administrator than with the doctor and man of science. He was afraid, however, that he had not the hardihood to enter into the controversial atmosphere which surrounded the question. He left it to the conference to decide to what extent the malarial mosquito had been practically vanquished in the past or can be utterly defeated in the future. Much must depend upon the development of sanitation, upon carefully considered organisation, and last, but not least, upon financial possibilities. But however that may be, while readily admitting the value of the great discoveries to which he had referred, we are mercifully in

our struggle with malarial fevers not merely confined to the direction of an anti-mosquito campaign. He referred the direction of an anti-mosquito campaign. to a prophylactic administered upon systematic and wellthought-out lines, and quoted Professor W. Osler's results in Canada, the marked successes on the Panama Canal, and the distribution of quinine in the shape of comfits and chocolates in the malarious districts of Italy. Colonel Braide's satisfactory results due to prophylactic treatment in the prisons of the Punjab were also enumerated. The conference had before it two important facts, Major Ross's discovery of the actual cause of malaria and the evidence which Lord Minto thought they may assume to be incontrovertible that where quinine can be systematically administered as a prophylactic a very general immunity from malaria will result. It would rest with the conference to decide by what means the knowledge of these two great facts may best be utilised. He only attempted to outline the general conditions of a problem of imperial magnitude inasmuch as it affected the health and happiness of a great country, the successful solution of which problem must depend upon the united efforts of the administrators and the varied interests which the members of the conference were assembled to represent. It was his earnest hope that the results of the deliberations of the conference may be the inauguration of a campaign against what we now know to be a preventible disease, and which campaign would confer a great boon upon the people of India, and although the campaign must of necessity be long and hard fought he opened the conference in the firm belief that it would eventually be crowned with success.
Lieutenant-Colonel J. T. W. Leslie, M.B., C.I.E., I.M.S.,

Lieutenant-Colonel J. T. W. Leslie, M.B., C.I.E., I.M.S., then delivered an introductory address, sketching the positions of the problems which would be placed before the conference.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday.

ON Oct. 31st collections were made at nearly all the churches and chapels in the city and neighbourhood in aid of medical charities. 17 charities participate in the proceeds. 283,000 cases were treated by them last year, as compared with 271,000 in the previous year. The increased expenditure necessitated by this larger number of cases, and the fear that the depression in trade and the numerous heavy calls that have been made during the year in support of the various philanthropic agencies might result in diminished collections, caused a special effort to be made by the organisers this year. The full returns have not yet been made, but it appears that last year's total of £5119 will be exceeded.

Health of Staffordshire.

Dr. G. Reid, the medical officer of Staffordshire, has just issued his twentieth annual report. A question of great importance to the inhabitants of the districts through which the River Tame flows is the condition of the watercourse. There has been a pronounced improvement in recent years through the efforts made by the Birmingham, Tame, and Rea drainage board in extending the area of the biological filters. Infantile mortality in the county still continues to decline, but there are five urban districts in which the mortality is more than 170 per 1000 births. Tunstall stands at the top of the list, with 209 deaths; Darlaston is second, with 200; Burslem and Longton have each 183; and Fenton has 179. Strong comments are made concerning the sanitation of Darlaston. It is one of the worst privy-midden towns, and in regard to the Notification of Births Act, Dr. Reid says that unless the district council determines to adopt the Act it will become a question whether the county council should not bring the Act into operation. Vaccination is very inefficiently performed in many districts of the county, and it is evident that the facility offered for obtaining exemption certificates has already had serious consequences as regards the number of children protected against small-pox.

The University.

The following appointments to the staff have been made: Mr. J. Sholto Cameron Douglas, M.A., M.B. Oxon., lecturer

THE PROPERTY OF THE PROPERTY O

THE LANCET OFFICES 423 STRAND, LONDON, W.C.

Reduction in the Price of The Lancet

The Manager begs to announce that with the New Year the price of The Lancet will be reduced to 6d. The Annual Subscription will also be reduced—to One Guinea for the United Kingdom and for Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month*; and to 25s. for the Colonies and Abroad.

For some time past it has been felt that the price of The Lancet, which has remained at 7d. for the past fifty years, is not in accordance with the progress of modern newspaper development; but sentimental objections to any change on the part of the late esteemed Proprietor of The Lancet, who lived to an advanced age, stood in the way of making the reductions at an earlier date.

In all other respects The Lancet will remain exactly as before, save in those features where it can

Subordinates claiming this rate can obtain from their Commissioned Officer a Certificate stating their rate of pay and allowances, and can forward it to The Lancet Offices with a request to be placed on the Subscribers' List.

be improved. It will continue to be a perfectly independent Journal, representing no sort of clique or particular school of thought, and serving no private aims whatever; for the interests of The Lancet must ever be identified with and be inseparable from those of the great body of the practitioners of medicine throughout the World.

Order Form

(This Form can be filled up, and the whole Page be detached at the perforation on the right hand side of the Page.)

To the Manager of The Lancet, 423 Strand, London, W.C.

Please send me The Lancet weekly for months, commencing with the issue of January 1st, 1910, for which I enclose £:

Name	
1 ddyess	
Autos	
Date	

ANNUAL SUBSCRIPTION-Inland, 21s.; Foreign, 25s.

Copies will be supplied for Six Months for 12s. 6d. Inland and 14s. Foreign; and for Three Months for 6s. 6d. Inland and 7s. Foreign.

Cheques and Post Office Orders should be made payable to the Manager, Mr. Charles Good, and be crossed. "London County and Westminster Bank, Covent Garden Branch."

in pathology and bacteriology; and Mr. Leonard Doncaster, M.A., special lecturer in heredity and variation.

Hospital Appointments.

At Queen's Hospital the post of honorary physician, rendered vacant by the tragic death of Dr. A. Foxwell, has been filled by the election of Mr. Joseph George Emanuel, M.D. Lond., M.R.C.P. Lond., physician to out-patients at the Queen's Hospital and Midland Free Hospital for Sick Children. Dr. Emanuel formerly held the posts of pathologist to the General Hospital and resident medical officer to the Hospital for Diseases of the Chest, Victoria-park, London. At the General Hospital Dr. J. Sholto Cameron Douglas has been elected to the post of visiting pathologist rendered vacant by the resignation of Dr. James Miller, who has been appointed extra-mural lecturer on pathology at Edinburgh. The increase in the number of operations at the General Hospital has necessitated the services of a third anæsthetist, and Mr. R. H. Rollinson-Whitaker, F.R.O.S. Eng., has been elected to the position.

Midland Medical Society.

The first meeting of the session was held on Oct. 28th. Sir Lauder Brunton delivered an address on Vascular Changes in Later Life. Mr. Frank Marsh, the President, occupied the chair, and there was a very large attendance of members. Nov. 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Medico-Chirurgical Society.

THE first meeting of the new session of this society was held on Nov. 3rd. Perhaps the most interesting part of the proceedings was the expression by the President of the society's appreciation of the faithful and successful manner in which Dr. William Craig had acted as editor of the society's Transactions for 28 years, a labour which he was now relinquishing and passing on into other hands. It is proposed to present Dr. Craig with a tangible mark of the society's gratitude for the way in which he has worked for the society. Dr. James Ritchie, who has occupied the Presidential chair for the last two sessions, took for the theme of his valedictory address the importance of the constitutional element in diseases caused by bacteria, and referred to various interesting illustrations taken from cases in his family practice. Dr. Byrom Bramwell was then called to the chair and was warmly welcomed by the members present

Lord Hugh Ceoil at the University of Edinburgh.

The Associated Societies of Edinburgh University had their session opened on Nov. 4th by an address delivered by Lord Hugh Cecil, the Honorary President of the societies. The address was delivered in the McEwan Hall, which was well filled, and the chair was occupied by Principal Sir William Turner, K.C.B., in the unavoidable absence of the Right Honourable A. J. Balfour, Chancellor of the University. Lord Hugh Cecil's theme was "Liberty and Authority." The address was listened to with great attention, and evidently appreciatively followed by the audience in spite of the closeness of the reasoning and of the fact that he spoke for an hour and a quarter with only notes to help him. The address was a plea for liberty and individualism, and were any criticism to be passed upon it here it would be that the converse could be presented perhaps with equal cogency. After the delivery of the address the lecturer was entertained to supper in the University Union.

The Administrative Treatment of Pulmonary Tuberculosis in Glasgon.

In reference to your annotation on this subject last week. I may point out that it has been decided to increase the number of tuberculosis dispensaries, and in connexion with this it is satisfactory to note that the parish council has intimated its willingness to assist the public health authorities in this direction by permitting the use of the parish dispensaries as district tuberculosis departments on certain days of the week. This, of course, is as it should be, and will make for economy.

Faculty of Physicians and Surgeons of Glasgow.

At a meeting of the Fellows of the Faculty held in the

the ensuing year. Dr. D. N. Knox is the new president, while Dr. James A. Adams has been elected visitor.

Sequel to the Colliery Dector Question in Fife.

Another conference between representatives of the Fife Coal Company and of the Fife and Kinross Miners' Association in regard to the dispute as to medical attendance was held last week. An agreement was drawn up which will at least temporarily remove the existing deadlock. It has been agreed that each man employed at the Fife Coal Company's collieries in the Kelty district shall nominate on the back of his pay-ticket, on a day to be afterwards named, the medical man whose services he desires for the next quarter, and a list of the names of the men will be sent to the practitioner who has been nominated by them. Quarterly each man will hereafter nominate on the back of his pay-ticket the medical man whose services he desires for the ensuing quarter. Pending a final agreement the 6d. per fortnight deducted for medicine and medical attendance from the date of expiry of the notices already lodged shall be retained by the company, to be divided later among the medical practitioners according to the nominations of the men. Although these terms have practically been accepted by both parties to the dispute it is believed that the question of the arrangement between the coal companies and the men in regard to the choice of a colliery doctor will now be raised all over the country.

Typhus Fever in Dundee.

There has been an outbreak of typhus fever in North George-street, Dundce, traced to a certain family, who are supposed to have contracted infection while attending the wake on a man who was said to have died from pneumonia. Everything is being done by the authorities that is possible to prevent further cases.

University College, Dundee.

The report of the Council of the College is satisfactory. this year showing the record in numbers, 128 men and 112 women. Of these 56 were medical students. The financial side is also satisfactory, total ordinary income being £12.902, expenditure £12,595, leaving an apparent surplus of £307. The system by which each professor participated in the emoluments from the class fees has now, with the help of the Carnegie Trust, been abolished. An appeal for assistance in further endowing several of the classes and for founding others is made by the committee.

An Infirmary Inquiry at Inverness.

At a general meeting of the managers of the Northern Infirmary at Inverness held last week the clerk read the report by the directors on the case of a well-known surgeon in Bristol, who had been a patient in the infirmary after a bicycle accident in which he had fractured his leg. A charge was made that the patient had been neglected by the medical man who sent him to the infirmary, who happened at the same time to be on the staff of the infirmary. A special subcommittee of the directors took evidence and made a full investigation into the circumstances. After considering the whole matter the directors submitted a lengthy report, in which they expressed regret that the case had been left to be treated by the house surgeon. So far as regards the initial treatment and the setting of the leg, and the fact that the medical man who sent the patient in did not go back to see him in the infirmary until after the case had been taken out of his hands, they considered that each case should have the continuous attention of the member of the staff under whose charge it was put until the patient was discharged. The house surgeon, they also considered, should have reported the state of matters to the surgeon in charge before calling in the assistance of another member of the staff. They added that the whole circumstances showed that the relations between certain members of the staff were strained, and that there was a want of harmony which should not occur in such an institution. The only satisfactory element in the case seemed to be that the patient did not suffer any bad effects in consequence of what took place.

Donations and Bequests.—The Secretary of the Bristol General Hospital has been advised that the sum of £1000 has been given to the hospital funds by an anonymous donor. This gift is peculiarly welcome at the present time when the ordinary funds of the hospital show a Faculty Hall last week the office-bearers were appointed for | deficit to which they are not accustomed.

(FROM OUR OWN CORRESPONDENTS.)

Cleansing of Dublin Streets: Financial Difficulty.

A SERIOUS sanitary situation has just developed with regard to cleansing the streets of our metropolis—a city never quite proverbial for general tidiness or hygienic propriety. The fact is all the more deplorable inasmuch as every discriminating observer must admit that real strides forward have been made of recent years; while the general diffusion of hygienic education and the great amount of attention given to the housing of the poor had led some of the more sanguine to hope that in the course of another couple of decades our conspicuous mortality would be cut down to an average level. But the effect of a recent decision of the municipal council has been the production of a report by the cleansing committee in which an explanation is offered to the Lord Mayor, aldermen, and burgesses of the city of the consequent necessity for a reduction of The movement, which is a downward one, its staff. has been in progress for some months. In the three months ending June 30th of this year the committee had stated that a reduction of its estimates by a further £3000 had placed the department in a very serious position, but that they hoped to be able to effect a saving of £2050 by reducing the street staff by 20 men, by dispensing with some temporary hands, by taking off the £300 allowed for men's clothes, and by effecting small economies in other ways. These paragraphs were deleted by the council, and further correspondence with the estates and finance committee led to an expression of opinion of the latter body that after the rates had been struck on the basis of certain figures approved by the council, a subsequent resolution, which would have the effect of involving an expenditure not provided for at the time of consideration of the estimates, could not possibly be complied with. The law agent also wrote to the same effect. These communications caused the cleansing committee to hold a special meeting, the result being that further dis-oussion showed that the anticipated reduction of expenditure was greater than could be carried out. The council had resolved that the grant of clothes should be made to the men this year, and also that full pay should be given them during the first month of any illness; both items of proposed curtailment. But as no corresponding provision had been made when considering the estimates, the cleansing committee has definitely stated that it has no option but, having previously stopped all special work, to dismiss another batch of 57 men. In addition to the deplorable increase of unemployment which must result is the fact that the present reduced staff is not able properly to cope with the regular work of cleansing the streets—a fact which, unhappily, seems to be corroborated by the condition of every metropolitan thoroughfare at the present date. The committee has pointed out that the further reduction of its employees means that at the most important time of the year the work of cleansing the streets in the form of any general system must be abandoned, and it doubts whether it can even keep up the regular clearance of the dust-bins. It is very much indeed to be hoped that, in the interest of public health and of public taste, an early solution of this financial crux may be arrived at.

The Dublin Corporation and the Sale of Poisons.

At last week's meeting of the Dublin municipal council three members of the Pharmaceutical Society attended on behalf of that body to ask the council not to issue licences for the sale of poisons to seedsmen and other general tradesmen. The spokesman stated that there were 1500 persons on the register of the Pharmaceutical Society for Ireland who were legally qualified to keep open shop for the sale of poisons, and of that number 100 were carrying on business within the boundary of the city of Dublin, and that while a number of these were dispensing chemists pure and simple, a number of others carried on business as agricultural and horticultural druggists. It was submitted that the Pharmaceutical Acts had been passed solely in the interests of the public, because it was important that great care should be used in the handling of poisons, which should be carried out only by persons qualified for that purpose, as the pharmaceutical chemist

is, having been obliged to take out prescribed courses of lectures, to pass through a regulated course of study, and to undergo a searching examination. The municipal council, the Pharmaceutical Society argued, had been asked to grant licences to persons who had not shown that they were educated or qualified to handle those very dangerous substances in order that the public might obtain what they wanted in one "general" shop; but the society hoped and believed that the council would not permit such proceedings. The report of the public health committee on the subject was afterwards submitted to the meeting, and a motion was carried delegating the matter to the public health committee with instructions not to grant licences to other than pharmaceutical chemists.

Memorial to the late Professor Daniel John Cunningham.

On Nov. 3rd a meeting was held in the Medical School of Trinity College, Dublin, to take steps to establish a memorial to Professor Cunningham. The Provost occupied the chair, and among those who spoke were Professor James Little, the Dean of St. Patrick's, Sir Charles Ball, Dr. A. C. O'Sullivan, the Hon. Mr. Justice Boyd, and Mr. Edward J. Gwynn. It was decided that a memorial medal and prize in anatomy should be founded and that a portrait in bronze should be placed in the school. It was further resolved that the friends and former pupils of Professor Cunningham be invited to subscribe—subscriptions not to exceed £2 2s. The following were appointed an executive committee to carry out the wishes of the meeting: Professor James Little, Sir Charles Ball, the Hon. Mr. Justice Boyd, the Right Hon. Jonathan Hogg, Dr. A. C. O'Sullivan, Mr. E. J. Gwynn, Professor A. F. Dixon, Professor C. J. Patten, Dr. T. G. Moorhead, and Dr. R. A. Stoney. Friends and former pupils of Professor Cunningham who desire to join in the movement are requested to communicate with one of these.

Ulster Medical Society.

The opening meeting of the present winter session of the Ulster Medical Society was held in the Medical Institute, Belfast, on Nov. 4th, when the new President, Dr. J. J. Austin, delivered an interesting inaugural address on "Life Insurance," in which he discussed very fully and in a most valuable way such questions as the selection of an office, the special points to be attended to by medical men in the examination of those proposing to insure, the value or the reverse of personal history, and the comparative importance to be attached to signs of cardiac, renal, and pulmonary disease. Sir John Byers having spoken of the address as one of exceptional merit, a vote of thanks to the President was passed with enthusiasm by a large audience. The annual dinner of the Society will be held on Thursday next, Nov. 18th.

Dried Blood Serum as a Hæmostatic.

THE therapeutic possibilities of the dried blood serum of the horse formed the subject of a communication made by M. Robert and M. Chody at a meeting of the Therapeutical Society held recently. They said that although normal blood serum was known to possess hæmostatic and cicatrising properties its use was limited by the difficulty of obtaining a prompt supply of it in a fresh and aseptic state. They had, however, found a means of facilitating its therapeutic application by using the serum of horse's blood collected with aseptic precautions and immediately dried in a vacuum at a pressure of about two millimetres of mercury and a temperature approaching 0° C. Their experience and that of other observers who have tried this dried serum showed that it retained all its properties both in the dry state and after having been redissolved in water. Externally, it was useful in various profuse hæmorrhages, in epistaxis, and in hæmorrhage due to such causes as extraction of teeth, operations on the tonsils, removal of adenoid vegetations or hæmorrhoidal protrusions, rupture of the hymen, &c. Internally, the dried serum might be given in doses of one or two grammes daily in cachets to patients suffering from severe anæmia, hæmophilia, and other dyscrasic conditions attended with hæmorrhage.

Obstetrical Society of France.

A meeting of the Obstetrical Society of France was held in Paris last month. The principal subjects of discussion were as follows: Difference in the Temperature of the Lower Limbs (by M. Delestre); Results of Cultivations from the Blood in a series of dangerous puerperal infections (by M. Guéniot, with remarks by M. Cathala); Cyst of the Ovary in a parturient woman (by M. Lapage, with remarks by M. Pinard); a case of Myomectomy during pregnancy (by M. Corvelaire); Treatment of Aseptic Wounds by the lactic acid bacillus (by M. Jeannin); Retention of the Placenta and criminal abortion (by M. Boissard); Hysterectomy for Peritonitis following criminal manipulations in a non-pregnant woman (by M. Brindeau and M. Chirié); Asphyxia by Coal Gas of a woman at term, with recovery of the mother but death of the fectus (by M. Tissier); and Spontaneous Expulsion of a small uterine fibroma immediately after delivery (by M. Lacasse). Malignant tumours of the placenta formed the subject of a report presented by M. Brindeau and M. Nattan-Larrier, and there was a discussion in which M. Keifer, M. Brouha, M. Durante, and M. Paquy took part.

International Congress of Physiotherapy.

The Third International Congress of Physiotherapy will be held in Paris from March 29th to April 2nd, 1910, under the presidency of Professor Landouzy, Dean of the Faculty of Medicine. The work of the congress will be conducted in the seven sections as follows: (1) Kinesitherapy; (2) Hydrotherapy and Thermotherapy; (3) Climatotherapy; (4) Electrotherapy; (5) Radiotherapy, Radiumtherapy, and Phototherapy; (6) Cryotherapy; and (7) Dietetics. Further information may be obtained from the Secretary, Dr. Vaquez, 27, Rue du Général Foy, Paris.

Comparative Frequency of Tuberoulosis in the Offspring of Tuberoulous and Non-tuberoulous Parents.

At a meeting of the Société Médicale des Hôpitaux, held on Oct. 22nd, M. Pissavy communicated some statistics showing, on the one hand, that among 1428 children born to 469 non-tuberculous married couples, 123—i.e., 8 per cent.—became tuberculous; and, on the other hand, that among 292 children born to 100 married couples, in each of whom at least one of the parents was tuberculous, 93—i.e., 31 per cent.—became tuberculous. He also said that it seemed to be proved that in respect of the frequency of the transmission of tuberculosis there was no difference between town and country children.

Effects of the Suboutaneous Injection of Concentrated Tuberoulin in Non-Tuberoulous Children.

Subcutaneous injections of tuberculin in a concentration of 1 in 100 have been given by M. Mantoux to children who did not react to the ordinary dilute solution of 1 in 5000. The greater number of the children showed redness and sometimes a suspicion of infiltration at the place of injection; these symptoms, however, attained their maximum at the end of 24 hours and disappeared at the end of 48 hours. This was followed by an intradermal reaction which always developed on the second day. The injection of concentrated tuberculin, therefore, produced in non-tuberculous persons an early irritative reaction which was sharply distinguished from the late intradermal reaction. In the former case the tuberculin behaved as an ordinary irritant, whereas in the latter case it had a specific action. M. Mantoux gave details of his observations on Oct. 23rd at a meeting of the Biological Society.

Nov. 9th.

GUARDIANS AND TUBERCULOSIS.—At a recent meeting of the East Westmorland board of guardians at Appleby it was decided to renew the subscription of £60 to the Westmorland Sanatorium for Consumptives in order that the board might have the right to one free bed. The motion to this effect was only carried after some discussion, as three years ago the board adopted a resolution that the subscription to the sanatorium which had hitherto been paid should be discontinued.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Enforcement of the Vaccination Law.

THE Ober Verwaltungs-Gericht (High Court for administrative actions) has lately decided that the authorities have the right to compel a father (by the use of force if necessary) to have his child vaccinated. A man having been asked by the local police to obtain a certificate showing that his daughter had been vaccinated, failed to comply with the request, and was therefore fined by the police magistrate. The police then told him that they would be obliged to take the girl to the medical officer of health for vaccination. The father thereupon brought an action against the police, pleading that the question was settled by the fact of him paying his fine, and it was further argued in his behalf that the vaccination law, while rendering a father liable to a fine in the event of contravention, did not entitle the police to vaccinate a child by force. The court, however, decided that the action of the police was in accordance with the law, admitting that children might be lawfully exempted from vaccination for reasons of health. but not because the father happened to be opposed to vaccination. It would be at variance with the spirit of the law to hold that by once paying a fine a man may be allowed to obtain exemption of his children from vaccination, and in that way eventually to create risks for their health and that of his fellow-citizens.

Treatment of Erysipelas and Frostbite.

Professor Binz of Bonn, writing to the Berliner Klinische Wochenschrift of Nov. 1st, reports that 15 cases of erysipelas have been successfully treated by an ointment containing 15 per cent. of chlorinated lime (CaOCl₂), the result being that the fever disappeared on an average after two or three days, as compared with nine days under the methods formerly employed—namely, compresses charged with carbolic acid, corrosive sublimate, or alcohol. No complica-tions happened and no death occurred. Professor Binz on a former occasion had recommended the substance in question for the treatment of frostbite. He states that his method has been applied in a great many cases, in only one of which were there any undesirable symptoms produced. In this case the ointment after having been applied for five days gave rise to a bullous exanthem which spread from the hands to the skin of the face and the femur. It is therefore advisable, in the first instance, to employ an ointment of only 5 per cent. strength and only over a small area without ulcerations. The irritated spots should then be washed with a solution of sodium thiosulphate of 1 per cent. strength.

Examination of Tuberculous Sputum.

The Hygienic Laboratory of the city of Berlin has for some time examined free of charge samples of sputum sent to it by Berlin medical men. The town council, however, recently decided that the laboratory should charge for every examination 2 marks 50 pfennig, of which 1 mark 25 pfennig were to be paid previously to the examination. In explanation of this change it was pointed out that well-to-do persons could have their sputum examined by private laboratories, whilst for club patients and those of the necessitous classes the examination was undertaken by the anti-tuberculous dispensaries. The laboratory was also ordered to destroy the sputum in the case of the fee not being paid within The decision of the council was based on three days. the alleged great expense of examination of sputum made indiscriminately in every instance. This new departure caused a unanimous protest both in the ordinary newspapers and in the medical press. It was said that the prevention of tuberculosis was a matter of public welfare just as the prevention of fire was, and that the council might with as much reason abolish the fire brigade to save the expenses. The State laboratories are much more liberal than the municipal laboratory because they have examined and continue to examine every sample of sputum sent to them by a medical practitioner. The Deutsohe Medizinische Woohenschrift reminds its readers that in 1895 the Mayor of Berlin declined to make arrangements for bacteriological examination in suspected cases of diphtheria because it was not yet proved that Löffler's bacillus was really the only cause of

diphtheria. Universal disapproval has fortunately induced the council to withdraw its decision on the pretext that it was only provisional, but the narrow behaviour of the council has confirmed the general opinion that the appointment of a competent and salaried chief medical officer to the city of Berlin is highly necessary. At the present time medical questions coming before the council are usually handed over to one member who happens to be the only medical man having a seat on it, and who has interested himself in this work for many years. This system, however, is not without disadvantages nowadays when hygienic problems are so numerous and important.

Repeated Prosecution and Acquittal of an Unqualified Practitioner.

The repression of quackery is rather difficult in Germany. Unqualified practice itself is not punishable when no recognised medical title is assumed, and actions against such practitioners can be brought only on the ground of imposture or neglect of patients. The medical societies and the police do as much as they can to restrain quackery, but unfortunately their endeavours are hindered by the law courts where verdicts of "not guilty" are often given in most flagrant cases. An instance of this kind happened lately at Crefeld in Rhenish Prussia, a large industrial town, famous for its silk factories. In the neighbourhood of that town there lived a clergyman who has for many years conducted an unqualified practice on an extremely large scale, the annual number of new patients being estimated at about 15,000, who came not only from Germany but also from the neighbouring countries of Holland and Belgium. He does not charge fees but leaves it to the patients to pay what they think fit to the beadle who acts as his assistant and secretary. One of his favourite prescriptions was to put the patient into a clay-pit in the neighbourhood of his residence so that the people gave him the nickname of "Lehm-Pastor"—i.e., clay-priest. His diagnosis was only made by an inspection of the eyes of the patient, his theory being that he was able to see from certain lines or spots in the iris which organ was affected. He has been prosecuted 13 times but has always been found not guilty. Recently he was again charged with having caused the death of a patient by neglect. He had ordered a child suffering from appendicitis to be put into the clay-pit, the result being that death ensued from peritonitis. Before the court the hospital physicians and surgeons of Crefeld gave evidence that the clergyman's theory was absolute nonsense; the court thereupon decided that the defendant should prove in 20 cases at the Crefeld Hospital whether he was able to make a diagnosis by inspection of a patient's iris. The experiment failed utterly, for in no instance was a correct diagnosis made, and in one case the clergyman even overlooked the fact that the patient was blind. A verdict of "guilty" was generally expected, but to the great astonishment of the audience he was found "not guilty." An enormous crowd waited outside the court, and when the defendant appeared he was greeted with general applause and brought in triumph to the railway station. Far from making an end of the clay-priest's medical practice, the prosecution will, on the contrary, increase his renown. It may be seen from the foregoing that there is not much prospect of unqualified practice becoming extinct in the present state of the law. Nov. 8th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The New Surgical Clinic.

THE surgical clinic which was erected in 1875 and has been regarded by foreigners as one of the best equipped institutions of its kind on the continent, has of late years proved to be inadequate to present-day requirements. A new clinic has therefore been erected according to the plans of the architects, Mr. Korb and Mr. Giergl, acting on the instructions of Professor Dollinger. The building stands on the site of the old Botanical Gardens, and the surgical clinic took possession of its new quarters in October of the present year. The clinic consists of a basement, a raised ground floor, and two upper storeys, over which in the central part of the building there is a third storey, where the sleeping apartments of the nurses are located. For the distribution of

food from the central kitchen there is an underground tunnel having two special distributing rooms located at each end of the basement. From here the food is carried by lifts to the first- and second-floor dining rooms, while the bed-linen and dressing material are transported by two special lifts located in the right and left wings of the buildings. waste dressing material is transported in receptacles specially made for this purpose to the stoves, which are located in the basement, where there are also the following departments: (1) a store room for dressing material and plaster bandages; (2) sterilisers for dressing material; (3) a stove for burning cotton and other rubbish; (4) an orthopædic gymnasium; (5) an orthopædic workshop; (6) a dark room, which communicates by a spiral staircase with the photographic room situated just above it; (7) a room for the cages of small animals used for experimental purposes with staircase leading into the laboratory above; and (8) a mortuary, in which the bodies await removal to the pathological institute. The out-patient department is in the left wing on the ground floor, and here is also the room of the surgeon on data who affects for all also the room of the surgeon on data who affects are also the room of the surgeon on duty, who affords first aid in cases of emergency. Running along the whole length of the consulting-rooms there is a corridor, which is widened at each end, where there are chairs and benches for waiting patients. Into this corridor the consulting-rooms open, all of which are provided with dressing-rooms for males and for females. Out-patients attend in one or other of the following sections: (1) a section in which wounds, abscesses, and superficial inflammations are treated, the medical students being admitted in groups of 10 or 12, changing fortnightly; (2) a section for diseases of joints and bones and orthopædics, in which the students are admitted in groups of six; (3) a section for urological cases; and (4) a section for laryngeal and nasal cases. In these rooms minor surgical operations are performed, and after-treatment is given to patients discharged from the clinic but not entirely recovered. At one end of the corridor are the X ray laboratory and the photographic room, with the room for laryngeal and nasal cases between them. The separation of the X ray room from the photographic room is made purposely in order to prevent the sensitised plates from suffering under the action of the X rays. In the right wing of the ground floor there are: (1) the histological, chemical, bacteriological, and experimental laboratories; (2) the museum; and (3) the library and reading-room, together with the medical officers' dining-room and other apartments for their use. In the central part of the high ground floor, close to the main entrance on the left is the doorkeeper's lodge, and on the right a large lift in which there is room for one bed and three persons accompanying the patient. There is a wide staircase leading into the vestibule of the high ground floor. Into this vestibule the waiting-room, study, and dressing-room of the professor open. Into the left half of the vestibule a small lecture room opens for lectures delivered by privat-docenten and for certain courses of instruction. Opposite the main entrance of the large vestibule is the entrance to the large amphitheatre-like lecture hall, on both sides of which are waiting-rooms for male and female patients. Next to it there are the sterilising room and the room in which the patients are prepared for operation. The main lecture hall is lighted by a large window facing north. The space provided for the lecturer is so planned that operations can also be performed in it, and around this space there are 224 seats arranged in amphitheatre fashion. This lecture hall is connected with the right and left wings of the clinic by a covered glass corridor. The students come into the lecture hall from the first floor through a cloak-room, where there are lavatories for ladies and gentlemen. The male patients are accommodated in four large wards each containing 11 beds, four small wards each containing five beds, and four wards containing two beds. On the east side of the large wards there is a covered balcony, used as a recreation room, called the The left half of the floor is for septic and the right for aseptic patients, and in each wing there is a special room devoted to treatment and bandaging, and one dining-room, serving also as a recreation room for patients. The arrangement of the second storey corresponds with that of the first floor and contains the wards and rooms for female patients. In the northern part of the right wing is the aseptic operating theatre and on the left wing the operating theatre for septic cases. These theatres are arranged on the following plan:

(1) bathroom for patients; (2) preparatory room for patients; (3) instrumentarium; (4) sterilising room; (5) washing room for medical officers; and (6) operating theatre. All the floors are paved with glazed tiles and the walls are overlaid with white enamelled tiles. The sterilisers for instruments and dressing material are built in the wall between the operating theatre and sterilising room, and are accessible from both sides. On the flat roof there are terraces for the use of the patients; as a protection against the heat of the sun there are large roll-up awnings. These terraces can be utilised for light baths and sun baths. clinic still needs a building for the isolation of patients suffering from severe infectious diseases, and steps have already been taken towards supplying this deficiency. Nov. 7th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Institute of Tropical Diseases.

THE Registrar of the University of Sydney reports that an appointment has been made in connexion with the Australian Institute for Tropical Diseases. The headquarters of the institution will be at Townsville, Queensland, and the first director will be Dr. Anton Breinl. Dr. Breinl is a graduate of the University of Prague, where he occupied for some time a position as demonstrator of pathological anatomy. Latterly he has been connected with the Liverpool School of Tropical Medicine.

Tuberoulosis in New South Wales.

The Government statistician has issued a pamphlet analysing the mortality from tuberculous diseases in New South Wales. A comparison of death-rates for different types shows that pulmonary tubercle provides the great bulk of mortality. A table is given setting forth the salvage of life possible had the present-day rates prevailed through the last 33 years:-

			Actual deaths.	Salvage by present rates.		p	Salvage per cent. of actual.	
Males-Metropolis			11,504		5122	•••••	45	
Country			13,826	•••••	3159		23	
Females-Metropolis	•••		8909		3492		39	
Country			8593		1723		20	

Clinical Teaching at Sydney.

Medical students at the University of Sydney are in future to have the privilege of attending clinical teaching at the Sydney Hospital as well as at the Royal Prince Alfred Hospital. The latter institution is practically in the University grounds and while the number of students was small answered all requirements, but the school has shown such expansion that extra accommodation is needed. The following lecturers have been appointed at the Sydney Hospital: Olinical medicine, Dr. Sydney Jamieson; clinical surgery, Dr. H. L. Maitland; tutorial medicine, Dr. Hamilton Marshall; and surgery, Mr. B. J. Newmarch.

Telephone Mouth pieces.

An investigation was recently undertaken by Dr. F. Tidswell, director of the Bureau of Microbiology of New South Wales, into the question of the transmission of infection by telephone receivers. He examined 50 receivers and formed the conclusion that these mouthpieces are not a usual harbour for pathogenic germs. Diphtheria and tubercle bacilli were notably absent.

Asylum Pathologist.

The Victorian Government appoints an asylum pathologist under the present Lunacy Act, but the Faculty of Medicine has reported to the University Council that "the salary is not sufficient to induce a competent officer to surrender his whole time, and the duties include the making of post-mortem examinations in these asylums whenever the coroner so directs. In these circumstances a satisfactory result is impossible. Adequate research work is out of the question. The restoration of the duty of making post-mortem examinations to the medical staff of the hospital would greatly promote the scientific work, and full protection would be given patients if the coroner retained power in any particular case to instruct the neuro-pathologist or an outside medical practitioner to make a post-mortem." After consultation with the Inspector-General, the Faculty recomby the Government and the University Council, to devote his whole time to the work of research and teaching. salary named was £650 per annum, of which the department would provide £600, and £50 would be added by the University. The officer appointed would act as lecturer in the University.

Defective Teeth.

A partial examination of the teeth of State school-children in Melbourne reveals the fact that the proportion with defective teeth is very much the same as that in other countries. About 95 per cent. required more or less attention. Representations have been made by the Odontological Society as to the necessity of having one or more dental inspectors appointed to visit State schools.

The Keeping of Milk.

Mr. W. D. Pasey recently claimed in Western Australia to have discovered a new method of milk preservation by which milk could be kept fresh for practically an indefinite period. A bottle of milk stated to be five months old was some weeks ago handed to the Government analyst. It was kept a week further before being analysed, and the following report was submitted: "Total solids, 14.1 to 14.31 per cent.; fat, $4\cdot55$ per cent.; solids not fat, $9\cdot76$ per cent.; ash, $0\cdot73$ per cent.; specific gravity, $1\cdot34$. The milk has apparently been treated, but is free from any of the ordinary preservatives. It behaves in a peculiar manner in certain respects which cannot be explained without full particulars of the treatment it has undergone, but I see no reason to believe that it is in any way detrimental to health." Dr. F. Andrews, who was given a sample, said to be two months old, for bacteriological examination, kept it for four days before making his investigation. He reports that it gave almost the tests of normal milk. It formed almost normal junket, the clot being somewhat softer than that of ordinary milk, which might have great advantage from the standpoint of infant-feeding. 12 cultures remained sterile. He adds: "The most striking thing about the milk was the way it remained fresh after opening the bottle. Ordinary pasteurised milk keeps for only a limited time, and for a very short time once exposed to the air. I kept this milk exposed to the air for three days, and drank some of it then, and though I did not re-examine it bacteriologically, it was perfectly fresh milk so far as taste went."

Epidemics in Papua.

The Commonwealth Minister for External Affairs has received intelligence of severe outbreaks of disease among the native population of Papua. Dysentery and whoopingcough have been rife in the villages and many deaths have resulted. Medical aid was at once arranged for, and the principal medical officer proceeded in the schooner Merrie England to direct operations. It is estimated between 400 and 500 deaths have occurred, but the trouble appears to be now at an end. The Government has tendered special thanks to the Rev. Caleb Beharel of the London Missionary Society. Oct. 4th.

Medical Rebs.

FOREIGN UNIVERSITY INTELLIGENCE. Florence: Dr. Luigi Siciliano has been recognised as privatdocent of Medical Pathology, and Dr. Corsino Andrea Corsini as privat-ducent of Hygiene and State Medicine. - Freiburg: Dr. Wilhelm Trendelenburg, privat-docent of Physiology, and Dr. Franz Knoop, privat docent of Physiological Chemistry, have been granted the title of Extraordinary Professor.-Genoa: Dr. Arturo Morselli has been recognised as privatdocent of Psychiatry. - Göttingen: The late Professor Runge's chair of Midwifery and Gynæcology not having been filled up. Dr. Richard Birnbaum has been appointed to carry on the duties for the present. - Kiel: Professor Franz of Jena has accepted the offer of the late Professor Pfannenstiel's chair, but will not take up the duties until the summer session. They will in the meantime be carried on by Professor Hoehne. -Philadelphia (Jefferson Medical College): Dr. George E. Price has been appointed Assistant Professor of Neurology and Psychiatry. - Vienna: The charge of the Medical Department of the Polyclinic, vacant by the resignation of Professor von Stoffell, has been given temporarily to Dr. Rudolff mended that a neuro-pathologist should be appointed jointly | Kaufmann, and that of the Second University Gynzecological Clinic, vacated by the death of Professor von Rosthorn, has been similarly given to his assistant, Dr. Fritz Kermauner, for the current winter session.

Dr. Stanley B. Atkinson, J.P., was re-elected to the Stepney borough council last week.

Mr. R. Henslowe Wellington delivered a lecture upon Forensic Medicine and Coroner's Law on Wednesday last before the North-East London Post-Graduate College.

University of Sheffield.—The Council of the University of Sheffield has made the following appointments: Mr. George Wilkinson, B.A., M.B. Cantab., F.R.C.S. Eng., to the newly instituted lectureship in diseases of the ear, nose, and throat; Mr. George H. Pooley, B.A., F.R.C.S. Eng., F.R.C.S. Edin., to the lectureship in ophthalmology.

At a meeting of the Yeovil (Somerset) education committee held on Oct. 29th Alderman Sibly stated that after consultation with the chairman and the medical inspector of schools he had decided to defray the cost of providing a dental surgery for the treatment of school children, and he would also provide the maintenance funds for the first year. The committee awarded Alderman Sibly a hearty vote of thanks for his generosity.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general or quarterly meeting of the above association will be held at 3 o'clock on Tuesday, Nov. 23rd, at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Professor W. Bevan-Lewis. It will be preceded at 2 30 r.m. by the adjourned business portion of the last annual meeting. Members will dine together at the Café Monico at 7 P.M.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN. -The annual dinner of this school will be held at the Trocadero Restaurant, W., on Friday, Dec. 10th, at 6.45 for 7.15 p.m. Mr. H. Work Dodd will take the chair and there will be music after dinner. Applications for dinner tickets should be sent to Dr. A. G. Phear, 47, Weymouth-street, W., or to Mr. T. P. Legg, 141, Harley-street, W., not later than Dec. 1st.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.—The London County Council this week dealt with a part of the recommendations of the education committee for the medical treatment, through voluntary agencies, of London school children, referred to in THE LANCET last The main report advising the subvention of eight hospitals has not yet reached the Council, but on Nov. 9th it decided to accept the offer of the Hampstead Council of Social Welfare to provide gratuitously for one term medical treatment for children attending the Hampstead elementary schools. In this case it is proposed to establish two clinics, one in the out-patient department of the Hampstead General Hospital, and the other at some convenient centre in the western part of the borough. The treatment will be given by local medical men who are specialists in the ailments of children. We understand that the experiment is under the control of Mr. Hancock Nunn.

COMPLIMENTARY DINNER TO DR. W. A. DINGLE. -Dr. W. A. Dingle, the retiring Mayor of the borough of Finsbury, on Monday night last, to mark the close of his period of office, was entertained at dinner at the Holborn Restaurant. The chair was occupied by the Rev. Prebendary G. H. Perry, rector of St. Luke's, Old-street, himself an ex-Mayor of Finsbury, and among the others present were Alderman Enos Howes, J.P., L.C.C., Colonel Welby, L.C.C., the retiring Mayor of Holborn (Alderman Nolan Glave), Dr. W. Rawes, Dr. R. W. Gilmour, Mr. R. D. MacGregor, Dr. Gibbons, and Dr. A. E. Thomas, and a number of clergy. During the proceedings the chairman spoke of the very successful manner in which Dr. Dingle had performed the duties of Mayor, and asked his acceptance of a framed and handsomely illuminated address, the wording of which comprised a vote of thanks passed to him and the Mayoress by the borough council at its last meeting. Dr. Dingle was also presented with a silver epergne and Mrs. Dingle with a pair of bracelets.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

THE House of Commons, having read the Finance Bill the third time, has adjourned for a fortnight. The second reading debate on the measure will in all probability commence in the House of Lords on Monday, Nov. 22nd. It is expected that the session will come to an end in the early days of December.

Asylum Officers' Superannuation Bill.

The Asylum Officers' Superannuation Bill has passed the report stage in the House of Lords. Further changes were made in the text of the measure. Lord Monkbretton has taken charge of the Bill in the Upper Chamber, and has been in close communication with Sir WILLIAM Collins in regard to all the suggested modifications in its terms.

The Oaths Bill.

The Oaths Bill, which is designed to facilitate the practice of taking the oath by uplifted hand in courts of law, has received a third reading in the House of Lords. It has also passed through the House of Commons.

The London Milk-supply.

If it were not a serious matter there would be something amusing in the way the responsibility for the purity of London's milk-supply is being bandied between Parliament and the London County Council. It reminds one of the ancient game of battledore and shuttlecock, and the manner of playing is as follows. The London County Council inserts in its annual General Powers Bill clauses to enable it to exclude "dirty" milk from the metropolis. When the Bill is before Parliament the President of the Local Government Board promises to introduce general legislation, and on this understanding the Council withdraws its clauses. Pressure of business prevents the Government from carrying out its promise, and next year the Council's attempt to obtain for London what the country as a whole cannot succeed in getting, is repeated, and is met with the same plea as before. And so the game goes on, and infant mortality with it. This week the County Council decided to have another try next session to get its clauses through, and at the same time adopted some of the Government's ideas towards the solution of the problem, namely, the clause in the Milk and Dairies' Bill, 1909, which empowers local authorities to prohibit the sale of milk derived from cows suffering from tuberculosis with emaciation as well as those suffering from tuterculosis of the udder; and another which enables a qualified veterinary surgeon, if provided with an authority from the medical officer of health, to exercise the powers of inspection and sampling which at present are only exercisable by the medical officer if accompanied by a veterinary surgeon.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 3RD.

Medical Examination of Territorial Recruits.

Medical Examination of Territorial Recruits.

Mr. FLETCHER asked the Secretary of State for War whether he would explain why medical men who were Territorial officers received daily pay when in camp, but when deputed, as in March last, to examine recruits and men seeking promotion as non-commissioned officers, were told by their commanding officers that fees were contrary to regulations.—Mr. Haldane (by written answer) replied: No fee is prescribed; but a grant of 1s. is made to an association for each recruit passed. These grants form a fund from which fees for medical examination of recruits can be had if necessary. It is, however, anticipated that in most cases the medical examinations will be conducted by the Royal Army Medical Corps of the Territorial Force as part of their military duties, as was done in the case of the Volunteers. No officer of the Territorial Force is paid for duties outside camp or training.

THURSDAY, NOV. 4TH.

The Public Health Acts Amendment Act, 1907.

Mr. J. W. Wilson asked the President of the Local Government Board whether he would state the number of applications received from rural, urban district, and borough councils, respectively, for the adoption, in whole or part, of the Public Health Acts Amendment Act, 1907; and to what number of these the necessary authority had been already given by the Local Government Board.—Mr. Burns furnished the following written reply: The following statement gives the information asked for:—

receive	Number of applications received by the Local Government Board.			
Boroughs	130		103	
Urban districts (other than boroughs)	278	•••••	258	
Rural districts	5 5	••••••	45	
	463		400	

The Finance Bill and Asylum Grounds.

In answer to Mr. Nield, who asked the Chancellor of the Exchequer whether, under the terms of the Finance Bill, the undeveloped land of a county asylum used either for the purpose of the recreation of the patients or under cultivation for the supply of produce to the asylum would be chargeable either with increment tax or undeveloped land tax, Mr. LLOYD GEORGE replied: Clause 36 of the Finance Bill exempts

from both increment value duty and undeveloped land duty land held by a rating authority.

The Royal Army Medical Corps in Ireland.

Mr. ASHLEY asked the Secretary of State for War whether steps were being taken to ensure that officers of the Royal Army Medical Corps serving in Ireland should this year receive the full leave to which they were entitled by the regulations.—Mr. Haldane wrote in reply: Under normal conditions it will now be possible to give every Royal Army Medical Corps officer serving in Ireland throughout the year full leave. provided that he is willing to take it when the exigencies of the service permit.

N.B.— A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

AN EIGHTEENTH-CENTURY ACCOUNT OF THE "SNAKE STONE."

THE remarks upon the treatment of adder bites which we have published recently have inspired a correspondent to forward us some eighteenth-century papers describing the virtues of the "snake-stone," together with an actual example of those curious bodies which were once held in widespread repute as a cure for snake-bites and as a panacea for many other disorders. These interesting relics of antique medicine were found by our correspondent whilst rummaging in an Basex manor house. There are two MSS. One is an old invoice addressed, "For the Reverd. Mr. Durham at Upmington, near Rumford," on the back of this document are scribbled three notes, which read, "Serpentine Stone (Cobra) Snake, &c. Lay it on"; "See Dr. Brockers Nat. Hist. p. 388, vol. 3. Kircher's China, Illustrated, p. 80, 1, 2, Piedro de Cobra. Ogilvy's Japan, p. 304"; and "Cousin Eliz. Jones in her D. room about a qr. before 3 oc. July 9, 1779." The other document, which has begun to crumble from age, is headed "The other document, which has begin to crumote from age, is needed "The wonderful virtues of the stone called Pietra di Cobra, which comes from the Indies," and is signed "Swinton, E., Coll. Wadh., Oxon., Aug. 29, S.V. 1732," with the date repeated under the address "Liburni." The following is an extract from the four closely written quarto pages, which are acknowledged to be "translated from the Italian original printed at Bologna and Foligno by Nicolo Campitelli, Ap. 1732 "

"This stone is called Pietra di Cobra by the Italians, because the Portuguese give it that name, by whom it is frequently brought into Europe. These are found in many provinces of the East Indies, but chiefly in the Province of QUAMSA (or QUANG-SI) in China, as likewise in several parts of Indostan, certain it is that in these parts lie hid serpents most venemous with hairy heads, which are therefore called SERPI CAPELLATI, which are wont to be gathered with great diligence by Hormus or solitary men which are those Anchorets which are called Jogues or Joquess, which are philosophers or priests of the Idolatrous Nations of those countries: and in the heads of these serpents is this stone found, which has virtues so wonderful, and which we are going to enumerate.

1. The colour of this stone approaches near a black. Some of them are spotted with a sort of Ash colour or pale grey: in order to know whether this stone is genuine or counterfeit you must apply it to your lips, and if it sticks close to them, and is not separated without great difficulty, you may rest assured that the stone is genuine.

2. If you apply this stone to the Bite of any Venemous Animal, that is to the Puncture or Wound made by it, it will immediately stick to the wound so as not to be easily disengaged from it, and after it has sucked out all the poison will of itself fall off, leaving the place intirely healed, and the poison perfectly cured. And if after the stone be taken off, or falls off from the wound, it be put in a little Wine or Water, and be left there for a small time, it will emit all the Poyson (into the said wine or water) and being washed, may be reserved for another occasion.'

The next eight sections describe how the stone may be used to cure the bites of vipers, scorpions, wasps, tarantulas, and mad animals, and swellings caused by pricking thorns; how it will draw the morbid matter out of "Scrophulous Eruptions, Pestilential Bubos, malignant humours, or any such like disorders"; how it may be pulverised and drunk to expel poisons from the "more noble parts of the body," and how it will cure the venereal disorders and has been applied with the greatest success in the cure of impotence, "a small incision being first made over the Gland (a very dangerous experiment) that the stone may be thereby made to attract the more strongly. The twelfth section warns those who use the stone to throw away the milk or wine in which they may wash it after use, as these liquids become highly charged with poison in consequence; the thirteenth describes its use in "malignant fevers and other scute violent dis-tempers" in the East Indies, and the document ends with references to the writings of Father Athanasius Kircher, the "Flora Sinensis of Father Michael Boim, the "Mercurius Brasilicus" of Father Valentine Stanzel, and to other works dealing with the subject.

The "snake-stone" found with this document, which has been sent for our inspection, is a thin oval body a little more than an inch long and three-quarters of an inch broad. It adheres to the lips to some extent when applied to them, but not very closely. It is of grey colour with dark streaks, is of light weight and polished surface, and has the consistency of horn. We believe that snakestones were as a rule made from stags' antlers from which the animal matter had been removed by heat, but this was not their only origin. It is quite certain that they never came out of the head of a serpent, in spite of the traditional belief, which was held well into the last Indeed, the curative virtues of the "snake-stone" not finally discredite; until 1867, when Dr. John Shrott of Madras performed some experiments which were reported in THE LANCET of May 11th of that year. He obtained six large cobras and made them bite parish dogs, the snake-stone being immediately applied to the wounds, a proceeding which did not prevent the speedy death of the animals. In the course of these experiments Dr. Shrott found that the poison of a cobra was soon exhausted by frequent biting, and this observation is supported by a letter from Dr. M. Amsier on a case of adder bite which we printed in our issue of Oct. 30th. A fairly complete account of the "snake-stone" is given in Buckland's "Curiosities of Natural History," a book which we commend to the notice of any who may be interested and who may not have access to the work of the learned Jesuit Father Athanasius Kircher, that attracted the attention of "Cousin Eliz. Jones in her D. room" 130 years ago.

SWIFTHAND.

Sir Edward Clarke has always been interested in shorthand writing, and two years ago he published a system of his own invention. however, has nothing to do with "Swifthand," which at the first glance reminds one of the ancient Irish writing known as the Ogham alphabet. On closer inspection it differs considerably: it is not so cumbersome. The author seems to have contrived what an ancient author is only said to have done-viz., made "a cypher and character so contrived that one line without turns or circumflexes stands for each and every one of the 24 letters and as readily for the one letter as the other." Sir Edward Clarke's "Swifthand," in which every word is written as spelled, has an alphabet composed of oblique straight strokes with the slope of ordinary handwriting. There are 11 such simple oblique strokes, 9 more oblique strokes with a little horizontal short stroke or dash (which look like the figure 7 or an inverted 7) prefixed or suffixed, and one oblique stroke with a small hook prefixed. In addition, there are four tiny strokes or dashes in various positions and one little semi-circle (the "u"), to represent the vowels a, e, i, o, u. These vowels could be represented by imagining a trident whose prongs, starting from the left, would be a, o, and i, and whose base is e. These lines are of varying length in relation to each other and are placed in various positions-viz., resting on the line, hanging from the line, above or below the line, and through the line. This necessitates an accuracy and neatness in writing Swifthand that may limit its popularity. It is astonishing how quickly one can read the words after a little practice with such simple signs. It is an interesting book and a fair practical trial is the only way to appreciate the system, which might be of service to medical men in recording cases

AN INJURED EASTERN INNOCENT.

A CORRESPONDENT has forwarded us a copy of the Calcutta Statesman of Sept. 25th last containing a letter written by Babu Takur Das Pal to the markets committee of the corporation.

My prayer is (says the writer) that I have a milk-shop at the above address. At this shop I sell milk adulterated with water. I sell it in the condition I buy it from the market, and I do not water it myself. But the Food Inspector unable to stop sale of adulterated milk in the market unjustly threatens me. I have, therefore, publicly put up a signboard stating that adulterated milk is sold in my shop. I submit this for your Honor's information that the Food Inspector may not oppress me when I am not committing an offence.

In commenting upon this amusing document the Statesman says :-

From a report by the Health Officer, it appears that no fewer than 28 signboards have been put up in the Jorasanko milk bazaar bearing the legend "Milk with water is sold here" or "Milk mixed with water." The exhibition of these boards precludes the prosecution of the vendors for selling adulterated milk. "We can only seize under Section 503 for the purposes of taking before a Magistrate," reports the Health Officer.

We are used to the notices of certain milk purveyors in this country stating that every effort is made to supply pure milk, but that no guarantee is given of its purity, and such notices are bad enough, but they are sweet reasonableness itself when compared to the impudence of this self-pitiful Babu.

THE TOXICITY OF THE DIFFERENT VARIETIES OF STROPHANTHIN.

Owing to the interest which has been lately aroused in the administration of strophanthin by intravenous injection it is opportune to refer to a paper by M. Pedebidon in the Comples Rendus de l'Académie des Sciences of July 26th, wherein it is pointed out that the various botanical species of strophanthus yield strophanthins of widely varying potency. Strophanthus Kombé yields a crystalline glucoside which kills a rabbit in doses of ½ milligramme per kilogramme of body weight, when administered by hypodermic injection. Strophanthus gratus also contains a crystalline glucoside, and these two varieties of strophanthin are alike in toxicity and in physiological properties. Strophanthus hispidus differs from the other varieties in yielding an amorphous glucoside which is only two-fifths as toxic as the crystalline varieties. During the past two years the amorphous strophanthin has been used and recommended in Germany for Mitravenous injection, and it is

important to remember that it is less toxic than the crystalline varieties, which are liable to produce disastrous results if given in equal doses. It is interesting to note that the glucoside obtained from strophanthus Kombé is the next higher homologue of ouabaine, while that from strophanthus gratus is identical with ouabaine. From experiments on animals M. Pedebidon has found that the strophanthin last referred to is 20 to 30 times as toxic when injected into the muscles as it is when given by the mouth, and 43 to 86 times as toxic when administered intravenously. He remarks that the drug is well tolerated when injected into the muscles or given by the mouth even in high doses, no cumulative effect being noted after repeating the dose every day for 40 days. He recommends that the intravenous method of administration should be used only in exceptional cases, giving preference to the other two methods, particularly favouring the administration of granules of the standardised extract of strophanthus by the mouth.

PROFESSIONAL AMENITIES.

To the Editor of THE LANCET.

SIR,—I am sorry if anyone's feelings were hurt by my use of the term "raw" in its sense of "unpractised" (in administration of anæsthetics). I claim that those who give anæsthetics should be trained to use them.

I am, Sir, yours faithfully,
Whitehall-gardens, S.W., Nov. 8th, 1909.

J. VINCENT BELL.

THE HOSPITAL GAZETTES.

Guy's Hospital Gazette (Oct. 30th) contains more than an echo of the present political noise. It seems that the hospital residents as a body have been writing to the daily press to disclaim the partisanship shown in the recent Bermondsey by-election by a group of Guy's students as representing the general feeling of the hospital, a letter which was prompted by the impression given by certain newspapers that the hospital was identifying itself with the interests of Dr. A. Salter, the Socialist candidate, who was a brilliant student of Guy's. The letter was resented by some of the students who supported Dr. Salter, as appears from the correspondence in this number of the Gazette, but is condoned by the editor. It is obvious that a corporation such as a hospital must be strictly non-political, and we have always thought that medical men taking any part in events of public moment outside their own professional interests had better do so as private individuals. We have known, for instance, a student to address a letter condemning scientific research to a public print upon notepaper bearing the name of his hospital—an obviously improper proceeding. Another column of the Guy's Hospital Gazette contains a report of a students' debate upon the Budget, the principles of which were "strongly disapproved" by 44 votes to 19. Mr. Arthur Todd-White breaks further political ground by an article advocating the establishment of a Ministry of Public Health.—The London Hospital Gazette (November) describes a farewell dinner to Mr. C. W. Mansell Moullin on his retirement from the active staff of the hospital, and gives a portrait of that popular surgeon. The Clinical Supplement contains a paper on Eclampsia by Dr. R. D. Maxwell, and in the body of the paper Mr. T. S. Rippon describes an appliance for holding the jaw forward during the administration of ether anæsthesia. A description of a Yeomanry field-day and no tes on various topics are other tion of a Yeomanry field-day and no tes on various topics are other features of an interesting number. — The Middlesex Hospital Journat (October) contains Dr. J. S. Goodall's Introductory Address on "Walking the Hospitals," an abstract of which we have published, articles on "A Visit to a Convict Prison" by Mr. A. C. Morson, and on "The Officers' Training Corps" (which has received such excellent support at Middlesex), by Mr. A. E. Johnson. A supplemental sheet gives a spirited picture of Captain J. Bland-Sutten presiding at a smoking concert of the Middlesex Company of the Corps. — St. Bartholomew's Hospital Guzette (October) also contains an article St. Bartholomew's Hospital Gazette (October) also contains an article on the Corps' work in camp, besides an excellent account of "The Relationship of the Consultant to the General Practitioner" by a professional Polonius, whose advice on the mutual behaviour of the two classes when the general practitioner's patients seek the consultant's advice without acquainting their usual adviser of their intentions is worthy of close attention. Other ethical subjects are discussed in the November number of the same journal. --- St. George's Hospital Gazette (October) contains Dr. H. D. Rolleston's opening address, which is concluded in the November number. -Hospital Gazette also prints the October discourse which was delivered at that school by Principal H. A. Miers, an address upon which the editor founds his leading article. In the correspondence columns a member of the Indian Medical Service utters a measured warning concerning the changed prospects of his service and the probable limitation of civil appointments for British St. Thomas's Hospital Gazette (October) presents a reminder of the late alleged summer in the form of a frontispiece portrait group of its cricket team, and an account of the Interhospital Final which won them the cup in July. An anonymous contributor holds an interesting conversation concerning "A Ride along an Old Road"—to wit, the Kentish portion of Watling Street. We notice that the editorial staffs of these several journals have returned for the session in an unusually serious frame of mind, for we have been unable to discover the usual store of quips and cranks with which they are wont to lighten the medical reviewer's labours, such, for instance, as the neat copy of verses entitled "The Students' Guide to Osler," which appeared over the initials "S. S. in Guy's Hospital Gasette for Oct. 2nd.

Swifthand, A New, Simple, and Rapid Method of Writing. Invented by the Right Hon. Sir Edward Clarke, K.C Loadon: Simplin, Marshall, Hamilton, Kent, and Co., Limited. 1909. Pp. 44. Price 1s.

"DR. GUILLOTIN." To the Editor of THE LANCET.

SIR,-In stating that Dr. Guillotin "had nothing to do with" the machine that bears his name, Dr. Watkin W. Jones probably bases his statement on the fact that in the proposal made by the doctor to the Constituent Assembly on Oct. 10th, 1789, no mention was made of any instrument. According, however, to M. G. Lenotre (La guillotine, &c., d'après les documents tirés des Archives de l'État), "the orator suggested the use of the machine which has since borne his name" at a subsequent meeting on Dec. 1st of the same year. "With my machine," he said to the Assembly, "I could cut off your heads in an instant, and you would feel no pain."

Concerning the origin of the idea, M. Lenotre adds that an engraving of Bocchi of 1555 has often been reproduced, and that similar machines were represented by Penez, Aldegrever, and Cranach. Several engravings of the kind are in my possession, but the earliest I have met with is a woodcut from a fifteenth century copy of the "Vita di Sancti Padri, reproduced in various editions of the "Catalogus Sanctorum." One of these, a Lyons impression, is described in my "Early Woodcut Initials," the cut in question serving to depict the mode of martyrdom of several different saints. I am, Sir, yours faithfully,

OSCAR JENNINGS.

MORALITY IN RELATION TO HEALTH.

To the Editor of THE LANCET.

SIR,-I notice that in your reference in the last issue of THE LANCET to the paper "Morality in Relation to Health," by the Hon. Albinia Brodrick, you give the name of the publishers of the pamphlet as "The Free Press" at this address. The name should be The Nursing Press, Limited, who would be much obliged if you would kindly mention this in your next issue. Thanking you in anticipation,

I am, Sir, yours faithfully,

B. H. BLAKELEY, Secretary,

(for) The Nursing Press, Limited. 11, Adam-street, Strand, W.C., Nov. 9th, 1909.

R. G. and Licentiate are referred to Dr. Vincent Bell's letter on the preceding page

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

BOYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

Pathological Section (Hon. Secretaries—L. S. Dudgeon, C. Bolton): at 8.30 p.m.

Ordinary Meeting.

DERMATOLOGICAL SECTION (Hon. Secretaries—E. G. Graham Little, H. G. Adamson): at 5 p.m.

Dr. Arthur Whitfield: Localised Sclerodermia.
And other Cases.

BLEOTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton): at 8.30 p.m.

Dr. Reginald Morton: The Treatment of Nævi and other Cutaneous Lesions by Electrolysis, Cautery and Refrigera-tion, with a Demonstration on the Use of Solid Carbon Dioxide.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Dr. W. Thomas: (1) Œsophagostomiasis in Man (with specimens); (2) The Results of Experiments on Apes, Monkeys, Guinea Pigs, &c., when inoculated with Virulent Blood of Yellow Fever Cases or by the Bites of Infected Stegomyia calopus; (3) Mossy Foot of the Amazon Region (with microscopic specimens); (3) Notes on Stimson's Spirschate Found in the Kidney of a Yellow Fever Case. (With epidiascope demonstrations.)—Paper (with specimens) will be read for Dr. J. Numa Rat, St. Kitts, W.I., on the So-called Guinea Worm of the Island of Nevis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

Monday.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M., Lecture:—Dr. J. L. Bunch: Tubercular Diseases of the Skin and their Treatment.

TUENDAY.—4 P.M., Dr. C. T. Williams: Clinique (Medical). 5.15 P.M., Lecture:—Dr. W. Griffith (Leeds): On some Cases and Specimens of Unusual Diseases of the Heart.

WEDNESDAY.—4 P.M., Mr. T. P. Legg: Clinique (Surgical). 6.15 P.M.. Lecture:—Mr. Arbuthnot Lane: Operative Treatment of Fractures.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgical).
5.15 P.M., Lecture:—Dr. F. Warner: Backward Children and their Training.

FRIDAY .- 4 P.M., Mr. H. L. Eason: Clinique (Eve).

POST-GRADUATH COLLEGE, West London Hospital, Hammersmith-

Monday.—10 a.m., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 p.m., Medical and Surgical Clinics. X Bays. Mr. Dunn: Diseases of the Byes. 2.30 p.m., Operations. 5 p.m., Lecture:—Mr. Baldwin: Practical Surgery.

TUESDAY.—10 A.M., Dr. Moullin: Gynscological Operations. 12.15 p.m., Lecture:—Dr. Pritchard: Practical Medicine. 2 p.m., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 p.m., Operations. Dr. Abraham: Diseases of the Skin. 5 p.m., Lecture:—Dr. R. Morton: X Ray Examination of the Digestive System (illustrated by lanters shides). trated by lantern slides).

trated by lantern slides).

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children.
Dr. Davis: Diseases of the Throat, Nose, and Ear. 12.15 P.M.,
Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical
and Surgical Clinics. X Rays. Mr. B. Harman: Diseases of
the Ryes. 2.30 P.M., Operations. Dr. Robinson: Diseases of
the Ryes. P.M., Lecture:—Dr. Beddard: Medicine.

TRUBSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration
of Cases in Wards. 12 noon, Pathological Demonstration:—
Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays.
Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M.,
Lecture:—Mr. Keetley: Stiff Joints.

FRIDAY.—10 A.M. Dr. Moullin: Gyngeological Operations. Medical

REIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstration of Cases in the Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: A Common Cold.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Mr. B. Harman: Diseases of the Eyes. Dr. Davis: Diseases of the Throat, Nose, and Bar. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. 2.30 P.M., Operations.

LONDON SCHOOL Hospital, Greenwich. SCHOOL OF CLINICAL MEDICINE, Dreadnought

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Mr. R. Lake: Testing the Kar for Deafness.

Tuespay.—2 p.m., Operations. 2.15 p.m., Dr. R. Wells: Medicine. 3.15 p.m., Mr. Carless: Surgery. 4 p.m., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A m., Surgical and Medical. 12 noon, 8kin.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed swelverively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANGET should be addressed "To the Manager." ·

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

Until the end of the present year copies sent by post will be charged at the rate of $7\frac{1}{2}d$. inland and 8d. abroad.

Commencing with the issue of Jan. 1st, 1910, the rates of subscriptions, post free from THE LANCET Offices, will be :-

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANGET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

An original and novel feature of "The Lancet General Advertiser," is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded

should be forwarded

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager,

Mr. CHARLES GOOD, THE LANGET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANGET can be obtained at all Messrs, W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

An Address

OM

MALARIA IN INDIA.

Delivered at the Opening of the Malaria Conference, Simla, October, 1909,

By J. T. W. LESLIE, M.B. ABERD., C.I.E., LIEUTENANT-COLONEL, I.M.S.; SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA.

GENTLEMEN,—Before beginning the regular business of this Conference it seems to be desirable that you should have before you a rough sketch of the position of the problems of which we are to endeavour to find some solution -namely, the reduction of the amount of malarial infection in India and the mitigation of the results of infection. A reference to any recent Report of the Sanitary Commissioner with the Government of India will show that out of a total number of 8,000,000 deaths recorded during the year 4,500,000 were registered under the heading "fever." Many people assume that all these fever deaths are due to malaria, but a very cursory examination of the details of the statistics will show that this assumption is erroneous. If, for instance, we turn to the statistics recorded in Sind in 1907, we find that the total death-rate was 22.4 per 1000, including a death-rate from fever of 19.2. If all the deaths which appear under the heading "fever" had been due to malaria, all the other diseases to which flesh is heir caused only 3.2 deaths in every 1000 of the population. This is obviously absurd. If we now look at the statistics of Karachi for the same year we find that the total death-rate—unhappily very high owing to the prevalence of plague—was 49 per 1000, including a death-rate from fevers of 7 per 1000. As a matter of fact, the registration of vital statistics in India, except in a few of the towns, is carried out by means of an illiterate agency, and although in many provinces the total figures are surprisingly correct the registered causes of death are always very misleading. The heading "fever" represents pneumonia, tubercle of the lungs, diseases of the kidneys, and, indeed, all the so-called medical diseases, except diseases like cholera and small-pox of which the distinctive signs are unmistakeable by the people themselves. The total number of deaths registered under the heading "fever" is remarkably constant from year to year, the figure being a little short of 4,500,000, and the mean death rate rather less than 19.5 per 1000. During the last ten years death-rates have been raised owing to plague, but we may say that if, in a given year, the total Indian death-rate was 35 per 1000, four-sevenths of it, or 20 per 1000, would be ascribed to fever.

The question that at once occurs is, "What proportion of this death-rate of 20 per 1000 is due to malaria?" and obviously, in the circumstances in which deaths are registered, this is an exceedingly difficult question to answer with any degree of accuracy, but from the indications afforded by certain special inquiries, from the dispensary reports, and other sources, it has been estimated for the whole country at about one-fourth—that is to say, the mean death-rate from malarial fevers in an ordinary year, and taking the country as a whole, is about 5 per 1000. This means that in an ordinary year malaria causes about 1,130,000 deaths, and as in such a year it is not a very fatal disease, this number of deaths represents an enormous amount of suffering and loss of labour, often at the time when labour is of most value. It is impossible to judge of the amount of suffering or to frame an estimate of the economic loss, because we have no trustworthy data regarding the degree of fatality of the disease among the people. A rough idea of the extent to which death from malaria is preventable in India may be formed from a study of the effects of the disease in the Native Army and in jails, but, of course, in any comparison of the statistics referring to soldiers and prisoners with those of the general population, we must not omit to make allowance for the age and sex constitution of the populations compared, and for the peculiarly favourable conditions in which preventive measures act among bodies of men under skilled control.

The Native Army consists of picked men, who, when they are with their regiments, are looked after carefully in health No. 4499

and skilfully tended when sick. The admission and deathrates ascribed to malaria have declined in recent years, but during each of the 10 years ending with 1907 it may be said that 3 men in every 2000 died from its effects. Prisoners are greatly inferior to soldiers in physique, and they are subject to the depressing effects and monotonous routine of jail life. Moreover, there is a continuous flow into and through the prisons of individuals, many of them infected with malaria, taken from the lowest and poorest ranks of society. Still, far more stringent measures of prevention are possible in jails than in regimental lines, and the results are consequently better, so far as malaria is concerned. In each year of the decennium on an average 4 prisoners in each 3000 died from malarial fever.

When the deaths ascribed to malaria in the jails are closely investigated, it is found that in a considerable proportion of the cases death was due to a cause other than malaria, so that the mean death-rate of the ten years, which on paper is 1.30 per 1000, is in fact only about 1 per 1000—that is to say, the death-rate among prisoners from malarial fevers is about one-fifth of what it is among the general population. A comparison of a death-rate among prisoners with that among the general population is misleading owing to the numbers of children and old people among the latter, but preventive measures are by no means perfect in the prisons, and perhaps we may say that if we could place all the people in fairly good hygienic conditions, give them prophylactic doses of quinine during the fever season, and provide them with suitable food and skilled attendance when they are attacked, we should prevent three-fourths of the deaths from fever that now occur. This is perhaps rather speculative—certainly there are a good many "ifs" about it. Our experience in prisons does show this, malarial fever properly treated is by no means a fatal disease among adults. Last year (1908) malarial fevers were extraordinarily prevalent and fatal in North-Western India. During the year there were 20,039 cases of fever admitted into the jail hospitals throughout the country, and only 105 of those cases terminated fatally. Assuming that all the 105 died from malaria, which the post-mortem records show was by no means the case, this means that only 1 in 191 cases of fever ended in death, and this in a year when the fever was peculiarly deadly. Contrast this with the state of affairs among the general population in the United Provinces in 1908, when 1 person in every 24 died from fever—in that year mostly malarial. Why is it that a disease which is so rarely fatal to a prisoner should be so often fatal to a free man?

A very large fraction of the total mortality from fever among the general population occurs among children and the aged, and in epidemic years they suffer disproportionately, because in such years, for reasons which I shall presently mention, they have to suffer from privations which loosen their feeble hold on life. In the Punjab in 1908 the infantile death-rate from fever was doubled and the fever death-rates among children between the ages of 1 year to 10 years of age were more than doubled. While due allowance must always be made for the share of the total mortality occasioned by malaria among the very young, it seems to me that, in normal years at any rate, there is sometimes a danger of exaggerating it, for it is not uncommon to find practically all the deaths occurring in infancy attributed to malarial fevers. Now we know that, in temperate climates, where there is no malaria, the mortality in infancy, even in favourable circumstances, is high; and in a tropical or sub-tropical country with a very high birth-rate we cannot expect children to escape the effects of malnutrition, bowel complaints, parental ignorance, and other special dangers of childhood.

In normal years I believe many of the deaths which result from malarial fevers are directly due to the treatment, or rather want of treatment, of the eases. I do not refer to the neglect of medicinal remedies, but to the withholding of food. In this country and in some others it is an article of popular superstition that a fever should be starved and the sufferer and his friends believe that the taking of food brings on the attack of fever. Too often it is the sufferer that is starved and not the fever. In any place in which malaria exists meteorological conditions may determine a severe epidemic of fever, when the disease becomes not only much more common, but enormously more fatal than in ordinary years. When heavy rains precede a severe outbreak of fever they

cause floods, when large tracts of country are submerged, houses collapse, harvests are destroyed, and the poorer classes of the peasantry are not only thrown out of employment but are exposed to great privation and hardship. It is then that the mortality among children and the aged is so highmalaria, owing to the simultaneous occurrence of exposure and privation, has become a very fatal disease. obvious considerations, but there are others which have not yet been fully elucidated. The floods, of course, produce lasting pools of water in which mosquitoes breed, but a feature of these autumn epidemics is the suddenness of their onset, which, it seems, can be accounted for only by large numbers of mosquitoes being very rapidly infected.

In the towns in India, as in other countries, there are numbers of people who lead a hand-to-mouth existence; ill-housed, ill-clad, and ill-fed, they pick up a precarious livelihood in the unskilled labour market. Such people have unsuitable food at the best of times, and they have no savings, so that when anything occurs to check the demand for such work as they can do, the scanty coarse food becomes scantier and coarser and they and those dependent on them offer little resistance to malarial infection and readily succumb to its effects. Analogous conditions, as pointed out by Christophers and Bentley, may be artificially produced in any area in which anopheles mosquitoes can breed, when large numbers of labourers are collected in it under bad hygienic conditions. The majority of such labourers are free from infection, but are highly susceptible to it, a few are infected, and all are dependent on their daily labour for their daily bread. Infection spreads, and with it the inability to earn money to pay for sufficient food, privation added to malaria determines a severe attack, attacks are repeated, and here again the disease is a very fatal one.

The cause of malaria is a sporozoan parasite of which there are three species generally recognised. These parasites pass the sexual phase of their lives in certain mosquitoes and the asexual phase in the blood of man. The important fact in respect of the prevention of malaria is that in nature the parasites occur in both hosts and, so far as is known, nowhere else. Preventive measures are founded on this fact and have for their object the destruction of the insect host, the prevention of the transference of the parasites from one host to another, or the destruction of the parasites in the blood of man. It is unnecessary to enumerate in detail the devices which have been used to effect these objects; they all may, I think, be classified under three heads: (1) the extermination of mosquitoes; (2) the prevention of bites; and (3) the administration of quinine. The prevention of bites is useful as a supplement to more radical measures, but so far as this is effected by wire gauze screens and mosquito curtains, which are expensive and require careful handling, the use of the measure must be limited to the wealthier

Much, I believe, could be effected by improving the design of living rooms and dormitories. It seems obvious that a well-ventilated, white-washed room will afford less shelter during the day to mosquitoes than a dark, dingy room. Anointing the body with substances offensive to mosquitoes is useful on occasion. Of the two radical measures, one aims at the extirpation of mosquitoes by abolishing their breeding-places or destroying the eggs, larvæ, or mature insects; the other aims at destroying the sporozoon by the administration of quinine, and there has been much controversy regarding the merits of the two measures. It has always seemed to me to be unfortunate that so many of the writers who contribute their views on this controversy to the public press have not been at the pains to study the original accounts of the experiments on which any opinion of value must be based The consequence of so much wild writing has been to confuse the issue, and not only the intelligent layman, but even medical men have been led astray.

It is obvious, if malaria is due solely to the bites of anopheles mosquitoes, that the extirpation of these mosquitoes will abolish malaria. It will be admitted by everybody that the continuous use of quinine, even for a short time during the year, is inconvenient and unpleasant to the individual and difficult to carry out among a community. It is therefore evident that the best way to get rid of malaria is to destroy the mosquitoes. The only questions are, can it be done? and, if it can, at what cost? It has been successfully done at Ismailia, but in conditions which were extraordinarily favourable, such as, I fear, occur very rarely, if they occur

at all, in India. Ismailia was built about 35 years ago by the Suez Canal Company as a model town. It is situated on the shore of the bitter lake Timsah with the desert behind it. The water-supply is derived from the fresh water canal.

In his report to the Liverpool School of Tropical Medicine, published in January, 1903, Major Ross pointed out that almost the whole of the irrigation system of Ismailia is free from larvæ and is unfavourable to their propagation, and that "the waters which really occasion malaria are the most shallow and insignificant surface pools, which could be filled up and drained away without difficulty and without detriment to cultivation or irrigation"; indeed, he remarked, "mosquitoes can be extirpated with great facility at Ismailia, in fact, with much greater facility than in any other town I have seen." Fever is said to have appeared in Ismailia in 1877, but it was never severe, and only three or four pernicious attacks had occurred from the commencement of the epidemic until 1902. Major Ross says: "The illness does not appear to be of such a severe type as I have met with in parts of India and Africa, and no deaths have been reported." The population of the town is 7000 or 8000; the Canal Company is the controlling force everywhere; there are no prejudices to overcome, there is no lack of money; the soil is sandy and the rainfall averages less than 2 inches in the year. Compare these conditions with those of any malarious town you know in India. The Ismailia experiment proves that the extirpation of mosquitoes to a degree sufficient to abolish malaria is possible, and so far it is a valuable lesson to Indian administrators, but surely it is futile to say that because success was achieved at Ismailia it should be achieved in the same manner in Indian towns. have said nothing of the expense.

We may now turn to a place where operations against mosquitoes were less successful-Mian Mir. This cantonment was deliberately chosen by the Royal Society's Commissioners, to whom Major James was attached as a representative of the Government of India: (1) because malaria was prevalent in it; and (2) because it was thought that the conditions for the destruction of mosquitoes were favourable. The Royal Society's Commissioners' experience in Africa had led them to doubt the practical value of operations against mosquitoes in the moister regions of the world, but they thought that such operations would be successful in the semi-desert conditions of Northern India. Mian Mir differs from Ismailia in most particulars, two of which are of special importance—the soil is impervious and the rainfall averages about 22 inches. The first year's (1902) operations were carried out by Major James. His conclusion was that "mosquito destruction, if it can be carried out successfully, will effectually banish malaria," and "the chief drawback to mosquito destruction is its difficulty and expense." second year's (1903) operations were carried on by Captain Christophers. His conclusions were:

The destruction of anopheles within an area by attacking their breeding places is extremely difficult. Although large numbers of pools were filled up and drained, and millions of larvæ destroyed by oil, adult anopheles were still abundant.

The mere obliteration of local breeding-places is useless. In Mian Mir almost complete absence of breeding was ensured to a distance of over half a mile, but adults still appeared in large and increasing

over nair a mile, out addits som appeared in large and increasing numbers in the area.

A distinct effect was produced upon the malaria of troops and on the endemic index of the bazaars. This was, however, only evident in the beginning of the fever season, and could not be maintained.

The failure of the operations appeared to be due to the passage of adult anopheles into the area from without.

A great deal was learned from the operations in Mian Mir. Before they were undertaken it was thought that fevercarrying mosquitoes bred in still pools of water, and could fly at most for a few hundred yards. It was discovered at Mian Mir that fever-carrying mosquitoes breed not only in pools but in running water, and that they can fly for half a mile; consequently such operations as can be carried out by a mosquito brigade were of very little use in Mian Mir. The critics of the operations did not, however, pause to consider matters of this kind. "Why," they said, "did you limit your operations to an area of four miles?" "What," they continued, "is the use of filling up and oiling puddles when there are channels of running water in which anopheles breed?" It seems to me that this was hardly fair.

The second phase of the Mian Mir experiment began with the extensive works undertaken by the military authorities; the results obtained will. I hope, be fully examined elsewhere. Before leaving Mian Mir there is one matter to which reference must be made. It has been said that the failure of the operations at Mian Mir has led to the neglect

of anti-mosquito work in India. I do not think this is the case. All the Mian Mir experiment showed was that success in operations against mosquitoes is not so easily gained as some people say, and no one who reads the excellent reports by Major Ross on the work at Ismailia and by Major James and Captain Christophers on the work at Mian Mir will deny that this is correct. During the last 10 years the energies of local governments and municipalities have been very fully occupied in dealing with plague, and less money has been available for the prevention of malaria than might otherwise have been the case. But a great deal has been attempted. If we have erred in giving too much attention to quinine prophylaxis and too little attention to mosquito destruction we have erred in the best company. Professor Angelo Celli of Rome, whose experience is greater than that of anyone else, at any rate in Europe, finds that, although the destruction of mosquitoes is possible in the laboratory and in small areas, the difficulties in extensive areas are generally insuperable.

Important information regarding malaria in villages was obtained by the Drainage Committee appointed by the Government of Bengal in 1906 to inquire into the conditions of the drainage of the Presidency Division and their connexion with malaria. Captain Stewart and Lieutenant Proctor of the Indian Medical Service were the experts appointed to assist the committee. In the districts of Jessore, Nadia, and Murshidabad they found that malaria as estimated from the spleen rates of children under 12 years of age, was, on an average, much less prevalent in villages situated on the banks of live rivers and on dry land than in villages situated on the banks of dead rivers or bheels, while in villages surrounded by thick jungle the spleen rate (68.8) was more than twice as high as that (26.2) in villages with little jungle around them—the effect of the thick jungle being to afford shade from the sun and check the evaporation of water from small hollows in which mosquitoes breed.

The success or failure of minor operations against mosquitoes appears to me to depend upon the state of the drainage. Where drainage is perfect, as in the case of Ismailia, the inhabitants can exterminate mosquitoes with little trouble; but where drainage is non-existent or bad, as at Mian Mir, it is practically impossible, by any means at present within their reach, for the inhabitants to destroy the mosquitoes. In any scheme, then, which has for its object the removal of malaria from an area, the first step is to ascertain the condition of the drainage and, if it is imperfect, how it can be improved so as to prevent waterlogging of the soil, not only in ordinary seasons, but in seasons of extraordinary rainfall. In the drier parts of India it seems it is abnormally heavy rainfall that is the danger. Last year in the west of the United Provinces the monsoon rainfall was about normal, but all the rain fell in two months, and fever was severely epidemic; in Berar the monsoon rainfall was 24 per cent. in excess, but it took nearly four months to fall and fever was less prevalent than usual. Drainage schemes are costly and they require a long time to carry out, even when the funds are available, and in the meantime the choice must often be made between measures against mosquitoes and the administration of quinine-unless. as may often be the case, it appears to be advantageous to use both these measures.

In making the choice all the circumstances of the case must be taken into consideration. To take extreme examples. If we have a town containing a few pools which are the only sources of the anopheles mosquitoes infecting the inhabitants, it is obvious that the remedy is to drain or fill up the pools. If we have a small village surrounded by a swamp in which anopheles breed, it is evident that quinine prophylaxis is the best remedy. In India we have all the gradations between these two extremes, but those approximating to the village in the swamp are in the enormous majority. An obstacle that has stood in the way of quinine prophylaxis is the doubt entertained by the general public and some members of the medical profession of its efficacy. This doubt is in most cases founded upon experience-medical men have found persons who have apparently been regularly taking quinine get fever, and most practitioners have come across cases in which quinine seemed to fail to cure malarial fever, while instances are not uncommon in which the results of quinine prophylaxis in a community have been exceedingly unsatisfactory. Sometimes the cause of failure is not far to seek—the drug has not been taken at all, the dose has been

There are other too small, or it has been taken irregularly. instances, however, that are by no means easy to explain, and whoever has studied the recent researches into the fate of quinine in the animal body will recognise how thickly beset with difficulties the subject is and how great is the necessity for further research, particularly in this country, which differs so widely from Europe in respect of the food of the people, metabolic changes, and conditions of climate. It is possible that a race of malarial parasites that is immune to quinine may be developed. Fresh-water amoebse may be gradually habituated to salt water, the infusorian Stentor kept in a weak solution of corrosive sublimate becomes tolerant of a solution containing four times the quantity of the poison that is fatal to stentors taken from pure water. Trypanosomes frequently develop in an animal being dosed with atoxyl a race of trypanosomes that is immune to that drug, and they produce descendants in a new animal host which retain this immunity. Giemsa and v. Prowazek succeeded in obtaining races of Colpidia that could live in fairly strong solutions of quinine. The parasite of malaria is far more closely adapted to its normal surroundings than the protozoa I have mentioned, but it seems possible that quinine-fast plasmodia may be produced, and we may speculate regarding the nature of such an immunity and whether it would be retained after sexual reproduction and passage into a new human host. Men infected with a quinine-fast parasite would be in an unhappy position.

It appears, however, that the prejudice against the use of quinine as a prophylactic entertained by a few medical men is hardly logical. If it is admitted that quinine is the remedy for malarial fever and that it acts by killing the malarial organisms-propositions which few medical men will be found to deny-it is surely reasonable to believe that it will be as useful as a preventive as it is as a cure. When it is realised that it is fatal to the vegetative form of the parasite, but may be ineffectual against the sexual forms, it will be admitted that it is even more useful as a preventive than as a cure. There is much evidence accumulated in this country to show that quinine swallowed regularly in sufficient doses is very nearly a complete preventive of malarial infection, or at any rate of the clinical manifestations of malarial fever. The most striking evidence of the kind is afforded by Colonel Braide's experiment in the Punjab in the autumn of 1908. The use of quinine as a prophylactic was introduced into the Punjab jails many years ago by Colonel Bate, and its use in them has been continued with ever-increasing stringency and success. Colonel Braide attempted an experiment on a great scale in 1907, but he failed to get his orders properly understood, and it was certainly fortunate that his great experiment was reserved for the autumn of 1908, almost the most malarious in the history of the Puniab. During the four months August to November, 1908, every prisoner on admission to jail was given 10 grains of quinine in the presence of the medical superintendent, and thereafter received 15 grains once a week. The results were very remarkable. The admission rate from malaria, including in it the rate on account of "pyrexia of uncertain origin," was 173.5 per 1000, the lowest on record, and the malaria deathrate of the year was the lowest with one exception. That this result was not contrived by classifying cases of malaria under some other disease heading is evident when the general admission rates from all diseases are studied. In 1908 this rate was 581.2 per 1000; in 1907 it was 706.8; and the mean of the five years ending with 1906 was 890 5. success of this kind justifies a very critical examination of any reported failure.

I have laid stress upon the danger of comparing the statistics respecting the inmates of our prisons with the statistics of the general population, and I think it would be just as unsafe to believe that because quinine prophylaxis may, with considerable difficulty, be made a complete success in prisons it will be equally successful among the people. The prisoners are under great advantages, their lives are regularly ordered, they are well housed, well fed, protected against the vicissitudes of the weather, and rarely undergo any exceptional bodily exertion. Quinine is given to them systematically in sufficient doses under supervision, and when they are attacked by fever every means is used to ensure the quinine acting at an advantage. Among the general public many know that quinine is a remedy for malarial fever, and are eager to get it when they are suffering, but many are prejudiced against it, and probably the majority have never heard of it. We shall therefore have to take means to bring the advantages of quinine before all those who live in malarious places, and not only eradicate prejudices, but educate the people to use the quinine in sufficient quantity and at the right time. I fear these will prove to be very hard tasks. The best preparations for the use of adults and children will have to be selected, and probably much will depend upon the way in which the drug is dispensed. The correct dose must be determined, and I think it would be of advantage to issue the drug in tablets or powders equal to the minimum dose sufficient for prophylactic purposes, with directions that the single dose should be repeated a certain number of times at specified intervals as a cure.

It is essential, I think, that it should be recognised that the distribution of quinine cannot be made self-supporting, and in view of economy, if for no other reason, very careful inquiries will be necessary regarding the needs of different localities. In many places no quinine is necessary at all; in others it is required only for a short time in certain years; in others it is required every year, but only at a certain season, and in yet others there is need for its continuous use. It is clear, therefore, if we are adequately to carry out the distribution of quinine on a great scale, that special provincial agencies will have to be established for the work. The distribution of quinine is one of the questions with which this conference is specially to deal, so that it is not necessary to do more than mention some of the more important matters to be settled. Although our knowledge of the etiology of malaria and its treatment is fairly extensive, it is still wanting in continuity and completeness, and the scientific study of its epidemiology is only beginning. Some of the gaps in our knowledge regarding the possibilities in the life cycle of the parasite must be filled before we can hope to master the epidemiology of the disease to which it gives rise, and we cannot devise the simplest and best preventive measures until the epidemiology is thoroughly understood. As I have endeavoured to indicate, we have little exact knowledge of the distribution of malaria in the country, of the local conditions which favour it, and of the best means to render these causes inoperative. think the time has come when we should establish a permanent organisation for dealing with malaria in India.

It will be evident that the defects in our knowledge may be classified as follows: (1) questions of administration—e.g., the best agency for the distribution of quinine; (2) questions that can be solved by experts on the spot—e.g., the causes of disease and death and the distribution of malaria in a district; and (3) questions that can be solved only by highly trained experts with the resources of a well-appointed laboratory at their disposal.

The organisation I would propose is the following-

1. A committee in each province of three or more members personally interested in the malaria problem, enjoying the confidence of the local Government, and prepared to obtain information and supervise local inquiries. They should, perhaps, control the agency for the distribution of quinine. One of their first duties would be (in association with the provincial sanitary department) to ascertain the real causes of death in different localities, and to set in motion an inquiry in each district regarding the relation of the fever season to the drainage and rainfall.

2. Every autumn each provincial committee would delegate, under the orders of the local Government, one of their members to attend a meeting of a general committee in Simla. This general committee would consist of the provincial delegates, the Sanitary Commissioner representing the Government of India, with Major James as secretary.

3. The Government of India would appoint a scientific committee consisting of Lieutenant-Colonel Semple, Major James (secretary), Captain Christophers, and the Sanitary Commissioner, with power to add to their numbers.

A certain number of workers would be entertained under the Scientific Committee, and, when necessary, workers might be deputed to serve under the provincial committees. Such workers during the time of their deputation would, of course, be under the control of the local committee, but, in order that the purpose of the whole organisation should not be defeated, relations of mutual confidence would exist between the central and local committees, and there would be free interchange of views, not only on the occasions of the annual meeting, but by means of correspondence at all times.

3. Clinical Lecture

MYOTONIA ATROPHICA.

Delivered at the National Hospital for the Paralysed and Epiloptic, Queen-square, on Oct. 26th, 1909,

By FREDERICK E. BATTEN, M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN FOR OUT-PATIENTS, NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE; PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

GENTLEMEN,—The name "myotonia atrophica" will probably to most of you call up no clinical picture, and my endeavour will be to put before you the symptoms of this condition, so that you may have as clear a mental picture of this malady as you have of tabes or disseminated sclerosis. The name "myotonia congenita" has been applied to the disease originally described by Thomsen, and is often known as Thomsen's disease. The striking feature of that disease is that on attempted voluntary movement the contraction of the muscle which the patient wills to move is slower than normal, and that relaxation is also slow, so that the limb remains in a fixed position. The contraction is so strong that the antagonistic muscles cannot overcome it. If a certain voluntary movement is repeated several times the difficulty as regards movement becomes less and less. The action of walking is very commonly affected, and the condition may affect almost any muscle of the body. The condition is often hereditary and occurs in several members of a family.

In myotonia atrophica there are two striking features:

1) the myotonia: and (2) the muscular atrophy.

(1) the myotonia; and (2) the muscular atrophy.

1. The myotonia is shown more commonly in the difficulty in relaxing the grasp than in any other voluntary movement. In many cases it is limited to this movement. The greater the force of the grasp, the longer is the period of relaxation. The difficulty of relaxation is due to the continued contraction of the flexors and not to any weakness of the extensors.

2. The muscular atrophy is seen in the muscles of the face, and especially by the orbicularis oris and orbicularis palpebrarum, giving rise to the expressionless face which is so characteristic of the type of myopathy described by Landouzy and Déjerine. The masseter and temporal muscles are often affected. Atrophy, and in some cases the complete absence of the sterno-mastoids, is a very striking feature. The forearms, both flexors and extensors, are often feeble and wasted. The hand muscles are usually well preserved. Weakness of the thigh muscles is commonly present, and the vastus internus and externus show a marked tendency to atrophy, leaving the rectus femoris relatively intact. The muscles below the knee most liable to be affected are the anterior tibial group and peronei.

The disease commonly affects individuals between 20 and 30 years old, and males are more frequently affected than females. The myotonic symptoms usually precede the muscular atrophy. You will, however, obtain the best clinical picture from a consideration of the following case.

The patient, a man, aged 40 years, is the third member of a family of three. Both parents are dead, and as far as is known never had any complaint similar to that from which he suffers. His elder brother died at the age of 47 years from some wasting disease of the lower limbs which was diagnosed as "locomotor ataxia." He is said to have walked with a "steppage" gait and to have had especial difficulty in getting up and down stairs. He constantly complained of sharp shooting pains in the legs, but his gait was not unsteady. For many years before his death he had the same difficulty in relaxing his grasp as that of which his brother now complains. It seemed not improbable that he suffered from the same disease which now affects his brother. That the case should have been diagnosed as one of locomotor ataxia is not surprising, and it is of interest to note that in a case recorded by Rossolimo a similar diagnosis was originally made.

The patient's sister, a married woman, aged 46 years, has similar symptoms and similar atrophy of muscles to those of her brother, and she has had difficulty in relaxing her grasp

as long as she can remember, but the difficulty is rather less now than it was formerly.

The patient himself states that in 1900 he noticed that his thighs were getting thin. The wasting caused him no inconvenience till 1903, when at times his knees would suddenly give way whilst walking and he would fall. Recently he has had a stiffness about the legs when he first starts to walk, but this passes off after he has gone a few yards. He complains of a stiffness in the thighs when tired, and of sharp shooting pains down both thighs. For the last few years he has noted a steadily increasing weakness of his grip and his arms have become thinner. For many years, he cannot say definitely how long, he has had difficulty in relaxing his grasp. The difficulty passes off after repeated movement. He has had some difficulty in articulating his words when first starting to speak.

On examination the patient is a thin, spare man. His face is strikingly smooth and expressionless and the orbiculares palpebrarum are very weak, and attempts to keep the eyes closed against even very slight resistance are unsuccessful. The orbicularis oris is also very weak and he cannot whistle or blow out the cheeks properly. The face is generally very thin and there is some wasting of the temporal and masseter muscles. Both sterno-mastoids are completely atrophied, but the other muscles of the neck are well developed. The muscles of the shoulder and upper arm are neither wasted nor hypertrophied and all movements are good. There is some wasting of the forearm in both limbs and flexion and extension of the wrists are feeble. The grasp, however, is fairly good. There is no wasting of any of the small muscles of the hand and their power is not diminished. When the patient is asked to grasp an object he does so quickly and with fair force, but when he is told to let go there is a considerable pause before he is able fully to relax and extend the fingers. The first and second fingers extend first, and these are followed after an interval of some seconds by the third and little fingers. The difficulty in extending the fingers is due to the slow relaxation of the flexor muscles, and not to any weakness of the extensors. If the patient is now asked to repeat this movement he does so well and relaxation is more rapidly accomplished, and by repeating the movement several times he is able to relax his grip at once. If he simply flexes the fingers without force he is able to relax at once. The stronger the original grasp the slower the relaxation. The slow relaxation is not well shown in any other muscle. The patient walks in a natural manner, in spite of the fact that he complains of a feeling of stiffness when he first starts to walk. The knee-jerks are absent in both limbs, but the ankle-jerks are active and the plantar responses are flexor on both sides.

Electrical reaction.—The most striking feature on electrical examination is the very marked diminution of irritability of the muscles generally to the faradic current. It requires a far stronger current to produce a contraction in the muscles of the patient than in corresponding muscles of the normal individual. On first stimulating the flexor muscles of the fingers there is a brisk contraction and a relatively slow relaxation. The muscles cannot be said to give the typical myotonic reaction as described by Erb in Thomsen's disease.

The sister of the above patient shows a condition very similar to her brother. There are the myopathic face, the wasting of the sterno-mastoids, and the "myotonic grasp." The knee-jerks are, however, active. She considers herself a perfectly healthy woman with a "family failing," and only submitted to examination at my especial request.

Other cases might be mentioned, and for those who are interested in the subject I should refer them to a paper on the subject published by Dr. H. P. Gibb and myself in Brain, 1909. The striking features of the condition are the muscular atrophy, the myotonia, and the family nature of the complaint.

Historical.—Without giving a detailed description of the various cases which have already been published, the following short historical résumé may be of interest. In 1897 Pelizaeus described the case of a man with symptoms of Thomsen's disease associated with muscular atrophy. In 1899 Nogues and Sirol described a case of Thomsen's disease with muscular atrophy in a man aged 33 years. The symptoms of Thomsen's disease had been present since he was 17 years old, but the muscular atrophy only developed at the age of 28 years. In 1900 Hoffmann wrote a paper showing that muscular atrophy occurred in about 9 per cent.

of cases of Thomsen's disease. Since that time numerous cases have been published under titles which indicate muscular atrophy associated with myotonia (Thomsen's disease) and in some instances with myasthenia. The condition has been described under various names: myotonia with muscular atrophy (Lannois), muscular atrophy with the electrical reaction of Thomsen's disease (Lortat-Jacob and Thaon), Thomsen's disease with muscular atrophy (Nogues and Sirol), atypical forms of Thomsen's disease (Pelz), muscular atrophy with slow relaxation of muscles (Kleist), myotonia atrophica (Rossolimo, Fürnrohr, and others).

The name "myotonia atrophica" serves shortly to describe the salient features of the disease and is therefore the name here adopted. Objection may be raised to the term "myotonia," as it is often used as synonymous with Thomsen's disease (myotonia congenita). Myotonia is, however, only a symptom, and as such its use is here justified. Objection to the term "atrophica" may be raised, since the atrophy does not always occur in the muscles which exhibit myotonia, and it may further be urged that the myotonia should precede the muscular atrophy—a sequence of events which does not always occur.

Familial characters.—The familial characters of Thomsen's disease and myopathy are well recognised, and it is therefore not remarkable that the type here described should also present familial characters. The case which has here been described shows distinct familial characters, in that the sister is similarly affected, and it is almost certain that the elder brother was also affected. Hoffmann records the disease in a brother and sister, Pässler in two brothers, and Hunt in two and possibly three brothers.

Myotonia or myopathy. - The relation of the myotonia to the muscular atrophy is a point on which there has been considerable discussion—that is to say, whether these cases should be regarded as unusual cases of Thomsen's disease, or whether they should be regarded as cases of myopathy with the peculiar myotonic phenomenon. In the discussion of this point Hoffmann put forward the three following views: (1) Both diseases may develop independently in the same individual; or (2) the muscular atrophy may be primary and the myotonia develop as an added symptom; (3) the case may be primarily one of Thomsen's disease, in which muscular atrophy develops. Hoffmann argues that it is probable that the initial condition is myotonia, and that the muscular atrophy is secondary. In support of this view he quotes the cases recorded by Nogues and Sirol, in which the son had myotonia and muscular atrophy, whilst the father

had myotonia but not muscular atrophy. Myotonia does not always precede the symptoms of muscular atrophy. In

several of the recorded cases the muscular atrophy occurred

before the myotonia.

The distribution of the muscular atrophy is so striking and affects various members of a family in an exactly similar manner that it seems probable that the condition is more closely allied to the myopathies than to the myotonias. The presence of myotonia in association with other forms of muscular atrophy has been pointed out by Schlesinger, who has described the conditions in association with syringomyelia. It seems well at the present time to regard these cases as belonging to the great group of myopathy or muscular dystrophy; they do not, however, conform to any of the well-known types. The condition of the muscle of the face brings them into relation with the Landouzy-Déjerine type, whilst the condition of the lower limbs resembles rather closely the "distal" type described by Gowers and other writers. It would seem well until further pathological knowledge concerning the condition is forthcoming to regard them as a separate type belonging to the great class of myopathies.

Morbid anatomy and pathology.—The pathology of the condition is based on the examination of portions of the excised muscles by Rossolimo, and by the full pathological examination by Steinert published in this year. With regard to the portion of muscles excised, Rossolimo found great variation in the size of the fibres, from 23 to 195 μ . The normal fibres were small in numbers. The atrophic fibres were sometimes isolated, sometimes in bundles. The fibres instead of being polygonal in shape were rounded or oval, and the connective tissue was increased between the fibres. The sarcolemma nuclei were greatly increased in numbers, and became arranged in chains of varying

length. The transverse striation was altered in the smallest fibres.

The case recorded by Steinert is that of a man aged 44 years, in whom myotonic symptoms had been present since childhood. The father and a brother had also suffered from myotonia. In 1890, some 15 years before death, muscular atrophy began in the facial muscles, then in the sterno-mastoid and hand muscles, the general musculature of the body being involved. The myotonic symptoms showed themselves in opening and closing the mouth, in the movements of the tongue, and in most movements of the extremities. The phenomenon was also present in the movements of accommodation of the eye. The opening of the hand did not, in contra-distinction to the closing of the hand, show the myotonic conditions. The muscular wasting was general, but was especially noticeable in the small muscles of the hand. The patient had a typical myopathic facies, slight ptosis was present, and there was atrophy of the muscles of the jaw. The myotonic reaction was present in the muscles of the upper arm, but was not found in the extensor of the forearm. It should be noted that clinically this case differs very considerably from the one which I have described—the myotonia had been present since birth and was of a wider distribution than in most of the other cases recorded; the muscular atrophy was widespread and affected the small muscles of the hand.

The pathological examination showed the cerebral cortex to be normal. In the spinal cord there was degeneration of the posterior column in the lumbar region, and this could be traced up into the cervical region where it became limited to the column of Goll. The fibres of the extra-medullary posterior roots were in the lumbar region considerably atrophied, whilst the anterior roots appeared normal. The cells of the anterior horns were normal, and there was no change in the lateral columns of the cord. The muscles showed the changes which are commonly found in myopathic conditions -that is to say, there was an increase of the connective tissue nuclei between the muscular fibres, with simple atrophic degeneration of the muscle fibre, an increase of fat between the muscle fibres, and a general cirrhotic condition of the muscles.

Steinert discusses the relation of this disease to that of Thomsen's disease, and to myopathy. He holds the view which Hoffmann has already expressed that these are true cases of Thomsen's disease. There are instances in which perfectly typical cases of myotonia congenita have been affected with muscular dystrophy (Cases 2 and 3, quoted by Steinert). In both cases the myotonic symptoms were widely distributed, and existed from childhood and preceded the muscular atrophy. Steinert sums up the result of his investigations as follows: "The so-called myotonia atrophica is a condition in which a typical case of Thomsen's disease is affected with muscular dystrophy. The clinical picture of this muscular atrophy is sharply defined and highly charac-teristic. It occurs only in this form in Thomsen's disease. A number of more or less individual symptoms which occur only tend to make the clinical picture clearer. The comparative frequency of impotence and atrophy of the testicle should be emphasised."

In many cases, however, the myotonic symptoms are late in developing, and in not a few the myotonia has followed the myopathy. From a careful consideration of the clinical features of the disease and from the pathological evidence I should myself be inclined to regard these cases as belonging to the great group of myopathies. The question is still, however, an open one, and further clinical and pathological evidence is required before any definite statement can be made.

Prognoms.—The disease is usually slowly progressive, but in some cases it does not seem to advance, for the patients are able to carry out their usual occupations for many years

Diagnosis. - But little difficulty should arise with regard to diagnosis when once the leading features are recognised. The condition might be regarded as a muscular atrophy of a myelopathic origin, but the distribution of the atrophy is strongly against such a view. The condition might be regarded as a myotonia congenita (Thomsen's disease), and some authors have regarded these cases as aberrant forms of that disease. The weakness of the facial muscles and the character of the articulation may suggest the presence of myasthenia gravis, and some cases have been so described. The muscles do not respond readily to the faradic current; The Royal College of Surgeons in Ireland has never found

they do not, however, show the myasthenic reaction. From the various types of myopathy it is by no means easy to distinguish this group, for features are present which very closely resemble the facio-scapulo-humeral type of Landouzy and Déjerine, and also the "distal" type; the presence of the myotonic symptoms should separate such cases from these groups.

Conclusion.—In conclusion, the leading features may be shortly summarised as follows:—A patient, usually a male, between the twentieth and thirtieth year of life, begins to complain of weakness of the limbs and wasting of muscles. Some stiffness of muscles may also be complained of. On examination he is found to have weakness and atrophy of the facial muscles, of the sterno-mastoids, of the flexors and extensors of the wrist, of the extensor of the leg or dorsiflexors of the foot, and the striking myotonic phenomenon that after grasping an object he has difficulty Pathologically there is a general in relaxing his grasp. Pathologically there is a general cirrhotic condition of the muscles, such as is found in muscular dystrophy. The spinal cord may show some degeneration in the posterior columns, but the other portions of the nervous system are normal. My object will have been attained if I have given you a clear clinical picture of this disease. When once seen the condition is easy of recognition, and I trust it may fall to the lot of some one of you to work out in full the pathology of this condition. That variations from this clinical picture have been and will in future be described is certain, but the name "myotonia atrophica" will serve as a point around which this type of case may be collected and investigated.

ABSTRACT OF THE

Introductory Address

Delivered at the Opening of the Schools of Surgery of the Royal College of Surgeons in Ireland

By JOHN LENTAIGNE, F.R.C.S. IREL.. L.R.C.P. IREL.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

Mr. Lentaigne commenced his address with an expression of profound sorrow for the heavy loss which the College and the medical profession in Ireland had sustained by the death of the late professor of anatomy, Dr. Alexander Fraser, describing him as a man who combined scientific eminence with exceptional administrative ability and whose unwearied industry had been a marvel to all who knew him. He then congratulated the students who had been awarded prizes, and expressed for himself and for the Council of the College their deep regret that the pecuniary rewards which it was possible for them to give for such excellent work as had been done were so utterly inadequate, especially when compared with the rich prizes which were given by the Stateendowed rival medical schools. Proceeding in the next place to discuss the future prospects of the school he continued as follows:]

We are now approaching a period of the greatest difficulty and danger for the School of Surgery associated with the College. If we could persuade ourselves that these difficulties are nothing more than the natural result of fair competition—that is, of greater industry and capability on the part of our rivals—we should have no just ground for complaint; any such difficulties could be met in the future, as they had been met in the past, by equal or greater industry and effort on our part. Unhappily, our troubles are due to a very different cause. Our danger arises from the fact that as a result of a long existing political agitation the Legislature has passed an Act of Parliament which completes the endowment by the State of every medical school in Ireland except ours, which has been carefully excluded from Governmental favours and left absolutely out in the cold.

fault with the endowment of the other schools; medical education has grown with the vast progress of science to be such a difficult and financially unprofitable business that it may make a very reasonable claim to be assisted by the State when necessary. What we protest against is the unfairness and injustice of endowing one or more schools while absolutely ignoring the claims of another, which has done at least as good work, and against which no fault has been found. These rival schools will now be free from all possibility of pecuniary embarrassment, they will be provided with abundant funds for the equipment of laboratories and class-rooms, the salaries of their professors and lecturers will be paid for them, no inconsiderable number of rich prizes will be offered to them as bribes to entice students, and, worst of all, they can outbid and undersell the School of the Royal College of Surgeons by lowering the fees for lectures, degrees, and diplomas to such a point as must speedily starve and destroy our School. It is a matter of common knowledge that these things are actually being done, and this with funds supplied by the State, which should protect the interests of all alike, and to which all taxpayers are compelled to contribute. The scandalous injustice and unfairness of the scheme are so manifest that there is no need of an elaborate argument on the subject. When the Bill for the formation and endowment of the new Universities, which were to take over and absorb the four existing medical schools in Ireland outside Trinity College, was being introduced, the President and Council of the Royal College of Surgeons had full confidence that we should only have to state our case in order to have our grievance remedied. We therefore approached the Government and asked for such an endowment as would enable us to continue our work in the face of the new and increased competition. The sum we applied for was absolutely insignificant compared with the huge grants which were being voted for educational purposes for the new universities. In approaching the Government we felt all the more confident of success as the institution which we represent is an educational institution with a continuous record for a hundred years of good work done, absolutely non-sectarian and non-political, a common meeting ground for men of every religion and every shade of political thought, with equal privileges for all. The Royal College of Surgeons did not spare trouble, work, or expense in making its position clear to the Government. We sent several deputations to London, who spent many hours in the Lobbies of the House of Commons interviewing Members of Parliament, including the heads of both political parties and the Chief Secretary for Ireland, and finally an audience of the Prime Minister was obtained. Mr. Asquith paid in words a high and glowing tribute to the good work which had been done by the College and the School, but in deed he paid a very poor tribute to our intelligence, for he then proceeded to assure us that he did not think that either the School or the College would suffer by the new competition, but that if it were proved later on that they were really damaged, as was feared, then the Government might possibly reconsider the question, though he would not promise it. The result was therefore a complete failure. After all our trouble, loss of time, and expense we received in return only a number of high-flown complimentary phrases eulogising the good work which we had done.

[Mr. Lentaigne here discussed the question whether the failure of the negotiations with the Government was not due to the non-political attitude of the College and to the absence of support from any religious or political party with votes in Parliament. He illustrated the preferential State endowment of certain medical schools by a sketch of the results which might be expected from preferential endowment of one among several commercial firms, and continued

The Royal College of Surgeons is nevertheless determined to spare no effort to maintain the highest possible standard of efficiency in its School. During the past two months it has expended large sums out of its scanty funded capital in improving the School, and it will do everything in its power to maintain the unequal struggle as long as it would be possible; it will also agitate to the best of its ability, spreading far and wide, and on every possible occasion, the story of the wrong which was being done. My term of office as President will end in May next, but another will succeed me, and after him another again, and they and the Council will all continue the agitation until they get in the middle line below the umbilicus. The intestines were

redress. Owing to the peculiar conditions of professional life in Ireland the interests of the Royal College of Surgeons were bound up in the School. Every one of its 400 Fellows and every one of its 3000 Licentiates when receiving his diploma takes an oath always to uphold the honour and dignity of the College to the utmost of his ability, and each of them will abide by that oath.

TWO CASES OF INTESTINAL OBSTRUCTION IN WHICH A DOUBLE RESECTION OF INTESTINE WAS PERFORMED.

BY HUGH M. RIGBY, M.S. LOND., F.R.C.S. ENG., SURGEON-IN-ORDINARY TO H.R.H. THE PRINCE OF WALES; ASSISTANT SURGEON TO THE LONDON HOSPITAL; SURGEON TO THE POPLAR HOSPITAL.

THE two cases of acute intestinal obstruction which are here described presented so many interesting problems during their treatment that I considered their publication worthy of record. In both complications occurred which demanded numerous operations, and in both a double resection of intestine was ultimately required. The condition of carcinomatous stricture of the large intestine complicated by acute obstruction generally necessitates three operations before the condition is satisfactorily relieved. These include (1) exploration of the abdomen followed by drainage of the distended gut above the stricture; (2) resection of the growth when this is possible; and (3) an operation to close the artificial opening at a later date. In certain cases, where distension of the gut is slight and fæcal stasis has not occurred to any great extent, an artificial opening can be avoided by the formation of a lateral anastomosis. Unfortunately this is not often possible, especially in hospital practice. When it is possible, however, it affords a great saving of discomfort and danger to the patient.

When the stricture (as in Case 1) is situated at the splenic flexure of the colon, the opening for drainage may be made in any portion of the colon above or in the lower part of the small intestine. In Case 1 for purposes of drainage an extraperitoneal opening into the ascending colon was made in the right loin. This proved difficult to close satisfactorily at the third operation. When the obstruction recurred, however, it was re-opened easily and without danger of peritoneal infection. It is interesting to notice that this opening appears now to have closed completely, although it leads into a large cul-de-sac formed of small and great intestine. In such conditions a small mucous fistula generally persists, and probably the present closure is only a temporary one. In Case 2 the treatment of the large fistulous opening into the cocum was the most difficult part of the problem, and the treatment adopted, although successful, was somewhat drastic. It is of interest to note that this patient is now in sound health and well up to his normal weight, although deprived of most of his large and several feet of small intestine.

CASE 1.—The patient was a female, aged 31 years, whom I first saw in February, 1908, in consultation with Dr. Gordon Wilson. She gave the following history. Five days previously she had been seized with abdominal pain of a colicky nature; the pain was chiefly in the centre of the abdomen, but radiated towards the region of the cæcum. The pain made her feel sick and she had vomited several times. The bowels were confined and had only acted slightly after enemata had been given. The temperature was not raised above the normal. On examining the patient she did not appear to be very ill; her pulse was full and regular; the tongue was furred; she did not appear to be in much pain. The abdomen was somewhat distended all over, but this was most marked over the cæcum, and deep palpation caused pain in this region. The abdominal wall was not rigid. A tumour could not be felt in the abdomen. A rectal examination revealed a sense of fulness in Douglas's pouch, but no increased tenderness was caused by the examination. Her previous health had been good, and she gave no history suggestive of old intestinal trouble. An exploratory opera-

tion was advised and this was carried out next morning. First operation.—The abdomen was opened by an incision then seen to be distended, but most markedly in the region of the cæcum. The sigmoid colon was found to be small and contracted. The ascending colon was distended; on tracing the transverse colon across the abdomen a hard ringlike constriction was met in the splenic flexure. Owing to the general intestinal distension it was obvious that drainage was necessary. After a little consideration as to where the opening should be made it was decided to drain the ascending colon in the right loin. This was done without opening the peritoneum and a large quantity of fæcal matter was evacuated. The median abdominal wound had previously been sutured. A Paul's tube was fixed in the ascending colon and the patient was put back to bed. She made a good recovery from this operation; the loin tube drained well and the median wound healed soundly. Three weeks later I decided to excise the growth at the splenic flexure. For this purpose the patient was admitted into one of my beds in the London Hospital on March 19th, 1908.

Second operation.—The following operation was performed on March 27th, 1908. An incision was made through the left rectus muscle near its outer border about 3½ inches in length. The affected portion of the intestine with the growth was drawn out on the surface of the abdominal wall. The surrounding parts were protected with gauze. The growth with about 2 inches of intestinal wall on each side was removed, the mesentery having been previously ligatured

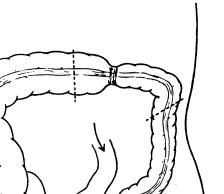

Fig. 1.

surrounding tissues. The edges of the intestinal opening were freshened and sutured together with catgut sutures. The margins were then inverted and a second row of chromic catgut sutures was applied. The muscles of the loin were next sutured over the intestine with chromic catgut and the skin edges were united partially, a drainage-tube being left at the lower extremity. This operation did not prove immediately satisfactory. The portion of the wound where the tube was inserted never healed completely, and a week after the operation slight feeal discharge occurred.

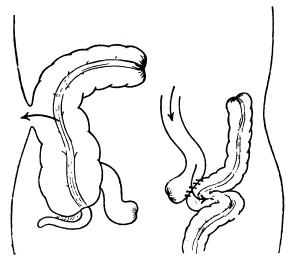

The patient was discharged from the hospital on May 21st in good health, but with a small sinus in the right loin. She came to see me at the London Hospital in the following October. She appeared then to be in very good health; she had gained over 1 stone in weight. The colotomy sinus had completely closed. The bowels acted normally and her appetite was good. She occasionally had aching pains at the site of the colotomy scar. The abdomen appeared normal

On May 25th, 1909, the patient again came to see me at the London Hospital, when she gave the following history. One month previously she began to have attacks of colicky abdominal pain in the lower abdomen and on both sides. This was relieved at first by taking aperients. Six days before admission she began to vomit and had vomited each day two or three times a day. The bowels had lately acted.

Fig. 2.

Shows the condition of the intestine before the fifth operation.

Shows the condition after the fifth operation.

and divided. Some enlarged glands were also found in the mesentery; these were dissected out freely. The divided ends of the intestine were then united by end-to-end anastomosis; a double row of chromic gut sutures were used for the union, and some additional fine silk sutures were superimposed at various points. The abdominal wound was then closed without drainage.

The patient stood the operation very well and had but little shock. The specimen removed showed a carcinoma of the scirrhous type encircling the bowel and causing almost complete constriction of its lumen. The glands were examined microscopically, but no secondary deposits were found. The patient made a good recovery from this operation. On April 6th I made the following note: "There is now only slight discharge from the lumbar colotomy opening. Formed motions are passed by the rectum. The sutures were removed to-day; some slight suppuration had occurred in the deeper part of the wound. The patient is comfortable and takes food well." Further progress was good and the abdominal wound healed soundly. The colotomy wound had appreciably contracted, but there was till daily discharge of fæces in small quantity. On May 1st, 1908, the following attempt was made to close this opening.

Third operation.—The patient was placed on the left side. An incision was then made on each side of the colotomy opening. The margins of the wound were dissected away and the opening into the intestine was freed from the

irregularly, and only very small liquid evacuations were passed containing some blood and a little slime. She had lost weight since November. The physical signs were as follows. The abdomen was somewhat distended; no peristaltic waves were seen. The colotomy scar looked red and was tender; there was distinct bulging in the right loin. The temperature was 100°; the pulse was 108, regular. The symptoms were evidently those of intestinal obstruction, probably due to recontraction at the site of the anastomosis.

Finirth operation.—On May 26th, 1909, my colleague Mr. Russell J. Howard, in my absence, opened the old colotomy wound and evacuated a large quantity of fluid fæcal material with immediate relief to the symptoms. The colotomy wound discharged freely after this operation and the patient's general condition was greatly improved. There was, however, no passage of fæces by the rectum, and the skin of the right loin became eczematous from the constant irritation. At the patient's request I decided to operate again and attempt both to relieve the obstruction and remedy the fæcal fistula.

Fifth operation.—On June 25th the following operation was performed. The abdomen was opened through the left rectus muscle by an incision below the umbilious to the left side of the scar made at the first operation. The position of the old anastomosis was explored with the fingers and a hard mass, evidently carcinomatous, was felt at the line of union.

It was localised and freely moveable and apparently could be excised without much difficulty. The small intestine was next sought for and traced downwards towards the cacum. Two clamps were then placed on the intestine about four inches apart, the lower one some three inches from the ileocsecal junction. The intestine was tied at two places with chromic gut sutures between the clamps, and the wall was divided transversely between these ligatures. Each end secured by the ligatures was encircled by a purse-string suture of chromic gut, and both were invaginated. The clamps were then removed. A lateral anastomosis by suture was then made between the proximal end of the divided small intestine and the lateral wall of the sigmoid colon. By this means the flow of fæces was diverted from the colotomy opening. Excision of the growth in the colon was next effected. The old anastomosis with the recurrent growth was freely removed as far as possible towards the descending colon on the left and the hepatic flexure on the right side. The mesentery containing some enlarged glands was also freely excised. The divided ends of the colon were treated in a similar way to those of the small intestine. The ends were secured by chromic gut ligatures tied round them, and each in turn was invaginated by chromic gut purse-string sutures encircling the wall an inch or two from the closed end. At the end of this operation the execum, lower portion of the small intestine, and the ascending colon were left closed at each end and communicating with the exterior by the right lumbar colotomy opening. (Figs. 1 and 2.)

The patient made a good recovery from this operation. The bowels began to act naturally 48 hours afterwards. The discharge from the loin greatly diminished and the condition of the skin rapidly improved. On August 13th the patient returned from a convalescent home in good condition. The colotomy wound has healed and no discharge has been noticed from it for the last seven days. The bowels act regularly without aperients. Her general health and appetite are good. She has gained 2 pounds in weight since the operation. Nov. 1st, 1909: The wound is still healed and

the general health is good.

OASE Z.—A male, aged 9 years, was admitted into the London Hospital on Jan. 16th. On the previous day, whilst at school, he was seized with acute abdominal pain accompanied by vomiting. He was sent home and put to bed, and chlorodyne was given. The pain and vomiting persisted. Two enemata were given with only a small result. As the acute symptoms did not subside he was sent up to the hospital next day at 8 P.M. His previous health had been good.

Condition on admission.—The boy was well n ourished, showing marked symptoms of shock apparently due to some acute abdominal lesion. The extremities were cold and the lips were pale. The pulse was small, 140 per minute; the temperature was 99° F. On examination the abdomen was found to be generally distended; the abdominal wall moved slightly on respiration. On palpation an ill-defined swelling was felt occupying the umbilical and right iliac regions. This was tender, not completely dull to percussion, and did not move during respiration. Over the rest of the abdomen distended coils of intestine could be felt. Nothing abnormal was felt by the rectum. The diagnosis of acute intestinal obstruction seemed clear, and the collapse and general condition of shock suggested the presence of gangrene of the gut. Shortly after admission the following

operation was performed.

First operation.—The abdomen was opened by an incision in the right semilunar line immediately over the tumour felt through the abdominal wall. When the peritoneum was opened a large quantity of blood-stained fluid escaped and a coil of gangrenous small intestine appeared. This portion was drawn out of the wound. It was found to be the lower part of the ileum. A coil of gut was found acutely twisted on itself, and across the neck of the twist a fibrous band was seen. This was fixed below in the pelvis, but its attachment upwards was not followed. The band was divided and the coil was untwisted. The portion of gangrenous gut was found to be constricted below about two inches from the ileo-cæcal valve, and above two and a half feet higher up. The gut was black and foul-smelling, the peritoneum had lost its gloss, and ash-grey patches were seen on its surface. A stout chromic gut ligature was carried round the healthy gut above the upper and below the lower constriction; intestinal

clamps were then applied on the gut between these ligatures. and the gangrenous portion was rapidly cut away. mesentery was ligatured with chromic gut and was divided piece by piece. A chromic gut purse-string suture was then passed round the intestine about 2 inches away from the ligatured ends. The latter were then inverted and secured by this suture. A lateral anastomosis by suture was then made between the lateral wall of the cæcum and the side of the ileum, some 3 inches from its proximal occluded extremity. The peritoneal cavity in the neighbourhood was cleansed with sponges and the abdomen was closed, a drainage-tube being left in the lower end of the wound. During the operation the patient was much collapsed and two injections of strychnine were given. Brandy and saline injections were given by the rectum on his return to the ward. The gangrenous portion removed was measured and found to be $2\frac{1}{2}$ feet in length. Fig. 3 shows the condition of the intestine after the first operation.

The patient rallied well from the effects of this operation. On the next day the pulse was 136 per minute; the temperature was normal. He had slight post-ansesthetic vomiting. Progress was uneventful for the next three days. Abdominal distension caused a good deal of discomfort, but was relieved by enemata containing turpentine. These brought away some fæcal matter and flatus was passed. On the sixth day after operation (Jan. 22nd) the upper end of the wound became acutely inflamed and hot fomentations were applied. On the next day the wound looked worse and had a sloughy greenish appearance. Two sutures were removed and a quantity of greenish pus with a strong fæcal odour escaped. Subsequently fæces were discharged from the wound and the

entire wound gradually gave way.

The condition on Yeb. 14th—i.e., one month after the opera-tion—was as follows: "The wound has gaped and fæces are passed several times daily through this opening. Enemata are given by the rectum every other day; these bring away a certain amount of fæcal material. The fæcal discharge from the wound is sometimes fluid, but often large masses of semisolid fæces are passed. The edges of the wound are beginning to show signs of irritation. The boy's general condition is good and he is not losing ground; he looks no thinner and

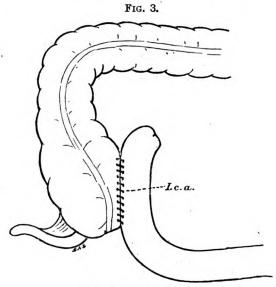

the pulse is good; he eats well."

The note on March 11th (7 weeks after the operation) said: "There is now a gap 1½ inches wide and 3 inches long owing to the separation of the wound edges; the floor of this gap is formed by the posterior half of the ileo-cæcal anastomosis. The anterior half of the anastomosis has entirely given way and has become firmly adherent to the edges of the abdominal The posterior wall prolapses occasionally. fæcal matter passes into the cæcum, as enemata given by the rectum sometimes remove fæcal contents. The majority of the fæces, however, pass straight out through the fistulous opening. A finger can easily be passed into the ascending colon and down the small intestine. The boy's general condition is good. He looks fatter and his temperature remains normal. The pulse is good. The skin of the abdominal wall round the wound is inflamed and pustular." On March 21st it is noted: "The boy is in much the same condition. Less fæcal matter is passed per rectum and there is a constant fæcal flow, generally fluid, but sometimes semi-solid, from the wound. He is not thinner and the pulse tension is good. The skin of the abdomen shows intense irritation from the constant fæcal discharge, notwithstanding the greatest care and attention in nursing.

The treatment of this fæcal fistula was now a rather difficult problem. Any direct attempt to close such a large opening seemed inadvisable owing to the septic condition of the wound margins. It was evident that unless the free fæcal discharge could be checked no improvement in the condition of the abdominal wall was to be expected. only course which recommended itself was that of dividing the small intestine above its junction with the cæcum and joining its proximal end to some portion of the large intestine beyond the fistula. The presence of the fæcal fistula and the septic condition of the skin made this proposed operation one of gravity owing to the great risk of infection of the peritoneum. However, this seemed the best line of treatment and accordingly the second operation was per-

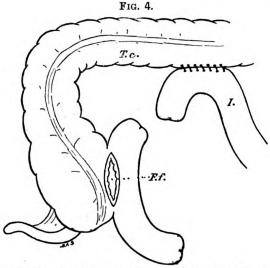

formed on March 28th, 1908. Second operation. - An incision 4 inches long was made below the umbilious in the middle line after the site of the fæcal fistula had been carefully cleansed and protected.

Many adhesions were encountered on opening the peritoneal cavity. The ileum entering the anastomosis was traced back and divided some 4 inches from its junction with the cæcum. Chromic gut ligatures were tied round the gut at two places and the intestine was divided between them. The two ends were then invaginated, the invaginated portion being secured by a purse-string chromic gut suture passed round the intestinal wall. The transverse colon was next sought

I.c.a., Ileo-cæcal anastomosis.

for and clamps were applied to it and the lower part of the ileum. A lateral anastomosis was then made by suture between these portions of intestine and the abdominal incision was closed. Fig. 4 shows the condition after this operation. The colon was not divided on the proximal side of the anastomosis; this step was considered at the time of operation but was thought inadvisable as an additional risk

Condition after second operation. T.c., Transverse colon. I., Ileum. F.f., Fæcal fistula at site of the lateral anastomosis.

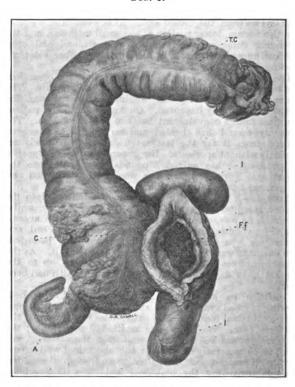

owing to the length of the operation and the child's condition.

The boy recovered well from the immediate effects of the operation. There were some abdominal distension and vomiting at first, which passed off after three days, and enemata brought away a good quantity of fæcal material. The fæcal discharge from the first wound entirely ceased from the date of the second operation. There was some suppuration in the median wound, but this yielded to fomentations with early removal of infected sutures.

The note on April 7th (10 days after the second operation) stated: "The ulceration and pustular condition of the skin round the first wound has entirely healed. There has not been any fæcal discharge at all from this wound since the second operation, but a little mucus comes away every day." On April 21st (about one month after the second operation) it is noted: "The median incision has healed well. The fæcal fistula remains as large as ever; the wound edges, however, are now quite healthy. Up to the present date no fæcal matter had come away, but daily discharge of mucus in small quantity. A few days ago a considerable prolapse of mucous membrane took place from the upper part of the wound, apparently from the ascending colon. To-day some fæcal matter was passed from the fistula, coming from the upper part of the wound and evidently from the ileo-colic anastomosis, passing backwards round the hepatic flexure and down the ascending colon."

This condition remained unaltered until May 15th. There was no tendency for the gaping fæcal fistula to close and occasionally fæcal matter was passed from it. The skin,

FIG. 5.

Parts of intestine removed at third operation. A, Appendix caci. T.C., Transverse colon. I, Ileum. c, Cacum. Ff., Fæcal fistula.

however, remained in good condition. The boy's general state was very good, the bowels acting well, occasional enemata being necessary. From time to time there was considerable prolapse from the fæcal fistula.

As the general condition of the patient was so good it was considered that an attempt should now be made to close the opening into the cæcum. The following alternative lines of treatment were considered. 1. An operation planned to directly close the opening. The skin was in sound enough condition, but it would have meant free opening of the peritoneal cavity and freshening of the edges of the wound which was still some 3 inches long by 1½ inches wide. Even if the sutures had held securely and the wound had united an undesirable state of affairs would have resulted. A cul-de-sac of large intestine extending from the middle of the transverse colon to the cæcum and the anastomosed portion of small intestine with two blind ends would have been formed. In this fæcal test-tube fæcal matter and mucus would probably have collected, which might readily cause subsequent trouble, perityphlitis, appendicitis, &c. For these two reasons, therefore, a direct closure of the fæcal

opening alone was considered inadvisable. 2. The second alternative was that of dividing and closing the colon on the proximal side of the anastomosis made in the transverse colon. This, however, was put aside as it would merely have prevented reflux of fæcal contents. The opening of the fistula was so large that it would probably have never contracted to any great extent, and probably a persistent mucous discharge would continue from the blind tract of bowel left-viz., a portion of the ileum, cæcum, ascending and hepatic flexures of the colon. 3. The third alternative which offered itself as the most certain but at the same time most dangerous one was: Division of the colon between the hepatic flexure and the ileo-colic anastomosis and subsequent removal of the entire portion of bowel left connected with the fistulous opening. After some consideration the last course appeared to be the only satisfactory one, and accordingly the following operation was performed on May 15th, 1908.

Third operation.—Gauze was first packed into the cæcal opening. An incision was then made in healthy skin round and above the mesial side of the opening and the adherent edge of the gut was dissected away from the skin, the peritoneal cavity being freely opened. The hepatic flexure and transverse colon were brought into the wound and packing was inserted to prevent prolapse of the surrounding intestines. A chromic gut ligature was passed through the mesocolon and tied round the gut a short distance to the proximal side of the ileo-colic anastomosis. A clamp was then placed half an inch nearer the hepatic flexure and the gut was divided between the clamp and the ligature. The ligatured end of the colon was next encircled some 3 inches from its extremity by a purse string suture of chromic gut and the blind end was invaginated and secured by this suture. Chromic gut ligatures passed by an aneurysm needle were used to tie off successive portions of mesocolon, working gradually downwards from the transverse colon to the cæcum. The wound was next prolonged downwards so as to clear the lower part of the cæcum and attached portion of the ileum. These were then pulled out of the abdomen. The mesentery of this portion of the intestine was ligatured with chromic gut and cut through. An incision was next made around the outer side of the opening in the cæcum and this portion dissected away from the skin and layers of the abdominal wall. The whole portion of intestine, comprising hepatic flexure, ascending colon, cæcum, and attached portion of ileum, was removed en masse. (Fig. 5.) Packs were removed and the abdominal wound was closed by through-and-through silkworm gut sutures and interrupted chromic gut sutures for the muscles. Catgut drains were left in the upper and lower ends of the wound in view of the probability of infection from the contaminated skin. This operation, which lasted 1 hour and 10 minutes, was well borne by the patient.

The after progress was most satisfactory; some suppuration, as was expected, took place in the wound, but this finally healed up soundly and the patient left hospital on June 25th, 1908. He is now in sound health.

Queen Anne-street, W.

STREPTOCOCCAL INFECTION IN DIPH-THERIA: OBSERVATIONS IN EIGHTY CONSECUTIVE CASES.

BY D. MORLEY MATHIESON, M.A., M.D. EDIN., D.P.H., LATE BACTERIOLOGIST AND ASSISTANT MEDICAL OFFICER OF HEALTH, BURGH OF LEITH.

THE frequent occurrence of isolated phenomena about the twelfth or thirteenth day of an attack of diphtheria was first called attention to by Sevestre and Martin. phenomena which they described consist of one or more of the following: (1) a cutaneous eruption (most frequently scarlatiniform, but in a few cases a simple erythema); (2) joint pains; (3) albuminuria; and (4) general constitutional disturbance, more or less marked. Sevestre and Martin, and later Roux, suggested that the frequency with which these phenomena developed on or about the thirteenth day seemed to indicate that they were the symptom-complex of a secondary disease, with an incubation period of 13 days, the infection occurring at the time of invasion of the diphtheria. They further suggested that the cause was organismal and probably streptococcic, reasoning from the facts (1) that they

frequently found evidence of mixed infection in the bacteriological examination of the throats of these cases; and (2) that they occasionally found similar symptoms develop in pure streptococcic infections of the throat. Antitoxin, they were inclined to believe, had the effect of lowering the resistance of the organism to the attacks of this secondary infection, just as suppuration is more liable to occur in a part poorly supplied with blood.

The following notes refer to observations made in 80 consecutive cases of diphtheria admitted to the Infectious Disease Hospital, Leith. A bacteriological examination of the throat of each case was made on admission and at intervals during the stay in hospital, and the clinical progress was recorded. In 9 of the 80 cases a marked streptococcal infection of the throat was found at one time or other in the course of the disease. Out of these 9, 5 developed symptoms corresponding to those described by Sevestre and Martin about the thirteenth day. In the remaining 71 cases where no streptococcal infection of the throat was at any time found, 2 showed epiphenomena about the thirteenth day. In other words: (a) 55 per cent. of the streptococcal cases developed "thirteenth day" symptoms; and (b) 2.8 per cent. of the non-streptococcal cases developed these symptoms.

These results, although they refer to only a limited number of cases, seem to suggest that there is some connexion between the streptococcus infection and the "thirteenth day" phenomena. (As to the part played by antitoxin in lowering the resistance of the tissues to the streptococcic invasion, it appears to be as probable that the lowered resistance is due to the diphtheria bacillus and its toxins, acting locally and generally.)

The following cases are illustrative:

CASE 1.-A woman, aged 21 years, was admitted with marked inflammation of both tonsils and a slight filmy patching on their inner surfaces and on the uvula. Swabs taken from the throat showed a few polar-staining Klebs-Löffler bacilli and streptococci in long chains. The temperature reached the normal in six days, during which time the throat symptoms gradually cleared up. On the thirteenth day albumin appeared in the urine and a fine punctate rash was seen covering the chest, the upper part of the abdomen, the upper arm, and the back, being very closely aggregated. There was no sickness or headache, and the tongue was not furred. Sore throat was not complained of; examination revealed streptococci still present, but no diphtheria bacilli. The albuminuria lasted for two days; the rash was of short duration, being practically gone on the evening of the day when it appeared.

CASE 2.—A boy, aged 9 years, came in with a localised patch on the right tonsil. A swab was taken and culture showed Klebs-Löffler bacilli and a few streptococci. The throat cleared up rapidly. On the eighth day an urticarial antitoxin rash developed, lasting 48 hours. On the four-teenth day the patient complained of some pain in the throat and of pain in both shoulders and in the left elbow. In the evening the temperature rose to 100 8° F. Examination of the throat showed a pure culture of streptococci. On the next day the temperature was down, the throat was not painful, and the joint symptoms, though still present in the left shoulder and elbow, were much less severe. On the sixteenth day the patient was quite well. A swab taken from the throat showed that a few streptococci were still

present. CASE 3.—A boy, aged 2½ years, on admission to hospital was found to have red, swollen tonsils, with some indefinite patching. Culture showed diphtheria bacilli, streptococci, and staphylococci. The temperature, which was 102 4° F. on admission, reached the normal on the third morning, and the local symptoms cleared up. Convalescence was un-

interrupted, except that on the evening of the twelfth day the child became restless and fretful. When the right ear was examined he cried, and was evidently suffering pain. On the following afternoon a discharge came from this ear, and relief was experienced at once. The discharge, which was scanty, continued till the fifteenth day and then stopped. Examination of the discharge showed streptococci and a few

The following is a brief summary of the seven cases in which

"thirteenth day" phenomena were observed:—(a) Streptococcal cases: (1) punctate erythema + albuminuria; (2) sore throat + joint pains + rise of temperature (100.8° F.); (3) otorrhœa; (4) punctate erythema; and (5) x 2

punctate erythema + rise of temperature (99.40). (b) Nonstreptococcal cases: (1) erythema multiforme; and (2) ,punctate erythema + rise of temperature (99.8°).

I have to thank Dr. W. Robertson, medical officer of health, Leith, for permission to publish the above observations. Norwich.

FURTHER REPORT ON A CASE THORACOSTOMY FOR HEART DISEASE.

BY ALEXANDER MORISON, M.D. EDIN., F.R.C.P. LOND. & EDIN.,

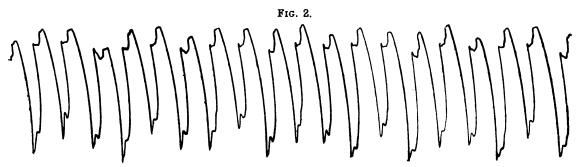

-SENIOR PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.

In THE LANCET of July 4th, 1908, there appeared an account of the first case operated upon in this country by thoracostomy for heart disease. The operation was not undertaken for the release of costo-pericardial adhesion but for excessive hypertrophy in aortic valvular disease associated with severe and frequent attacks of cardiac pain. The case

had occasional attacks of pain, usually at night, and which were relieved by inhaling nitrite of amyl. These attacks are, however, according to the patient, of much less frequent occurrence than prior to the operation. He has been taught the light trade of a hat-shape maker, and is endeavouring to earn his livelihood by this means. For a time he travelled to and from the City from his residence in Hornsey, but the journey was found to be too fatiguing for him. He reported himself at the hospital on July 5th, 1909, when the following note was made of his condition. He states that he has recently had a little more pain during the night when lying down, but that the great relief to his discomfort which followed the operation is still maintained. He looks well and weighs 8 stones 7 pounds, which is heavier than any previous weight except one, on June 25th, 1908, when he had just returned from a convalescent home. The pulse-rate is 96-114 and its rhythm regular. The instrumental determination of the blood pressure was omitted on this occasion, but a few days later was found to be 140 millimetres of mercury with the Riva-Rocci instrument for the systolic, and 80 millimetres for the diastolic, pressure. The ribless interval in the præcordia measures 3 by 4 inches, as it did soon after the operation—that is to say, there has

was under my care at the Great Northern Central Hospital, been no distortion or shrinkage of the decostated area. highly satisfactory and continue so. In the editorial comments on the case the desire was expressed to learn more of its future progress. As more than a year haelapsed since the operation, I am now able to afford this information.

Since leaving the hospital on June 6th, 1908, there has been no occasion for the re-admission of the patient. He has: reported himself from time to time, stating that he continued comparatively free from discomfort but that he still

and the operation was performed by Mr. Ewen C. Stabb heart pulsates powerfully in it and the hypertrophy of the on May 1st, 1908. The results of the operation were organ appears to have somewhat increased, the systolic impulse impinging rather more upon the seventh rib than it did a year ago. There is tactile systolic thrill over the aortic area to the right of the sternum and in the supra-sternal notch. There is a systolic and diastolic bruit most audible in the second right interspace and a systolic bruit of high pitch at the apex conducted towards the axilla and quite distinct from the aortic bruit. In the situation of the fifth left interspace there is still slightly diminished cutaneous sensibility. It may be remembered that this was very marked after the operation over an area of 2 by 4 inches, and was doubtless due to division of the intercostal nerves

in this situation. The respiratory rate is 30 and the lungs normal. The patient is otherwise healthy.

The accompanying cardiograms and sphygmogram show the nature of the pulsations, which, it will be observed, are vigorous and modified in delineation according to the site of application of the receiver, the larger and more powerful excursions of the lever being taken from a portion of the heart which received better the left ventricular thrust. The act of inspiration diminishes tactile cardiac impulse, as may be seen in the tracings.

The continued relief which has been afforded in this case from severe attacks of pain usually described as cardiac and regarded as one of the forms of angina pectoris is of interest in its bearing upon the etiology of that distressing symptom in such cases. A reference to details of the operation 2 shows that the interosseous muscles were removed within the area of operation from the fourth and fifth interspaces, and, as I have stated, anæsthesia to pain, touch, and temperature was induced over a considerable area by division of the fifth and sixth intercostal nerves. Although the degree of insensibility now is neither so marked nor so extensive as shortly after the operation, it may still be detected. Owing largely to the comparative insensibility of the viscera on handling them it has been suggested 3 that visceral stimuli provoking pain find expression in, or are referred to, associated areas in the somatic distribution of the nervous system, rather than in the organs themselves. The radiation of cardiac pain to the arm and in other directions lends some support to this supposition. In the case I have related, however, while the amelioration of the painful symptoms is very marked and the frequency with which attacks supervene greatly lessened, they nevertheless still occur and are relieved by the use of nitrites. As I have stated, the region in the thorax—the præcordia—so frequently the site of pain in such cases, has been considerably mutilated and anæsthetised, and in this case certainly I do not think we can ascribe the referred pain to the thorax. The patient, moreover, when asked to localise his pain, refers rather to the manubrium sterni than to the præcordia. It seems clear, therefore, that in this case the referred pain of the anginous attacks can scarcely be attributed to a reflex stimulation of the related somatic distribution, but to some stimulation of other nerve territories, in all probability endocardial or endovascular in situation. And what is true of this case I believe to be true also of many others.

It is one of the assumptions of current physiology that the viscera have little sensibility. Before dogmatising on this point it will be well to await a more perfect knowledge of the anatomy of the cardio-vascular nervous system. When that is attained we may also require some modification of our present conception of the physiology of visceral nervous sensibility. For example, eight years ago I found on examining the heart of a patient who had died from angina pectoris with coronary arterial disease that nerve cells existed in a coronary vessel internal to its muscular coat, and I am not aware that such intravascular innervation is recognised by anatomists, or a purely motor function attributable to cells in this situation. It may therefore be maintained that the reference of visceral pain to the somatic innervation is at least quite as much an assumption as its reference to the endocardium or endarterium. Present evidence in my opinion is rather in favour of the latter than the former assumption. But leaving in abeyance the decision of this point, the efficient cause of the attacks in the case I have related may be reasonably assumed to have been in great measure the muscular erythism induced by the costal stimulation of the hypertrophied and powerfully pulsating organ, and the indisputable fact is that thoracostomy has in this case been followed by notable amelioration of cardiac pain. This can scarcely be attributed, in view of the whole clinical history of the case, to any other cause than the removal of the costal barrier to freer and more expansive cardiac pulsation, in consequence of which the erythetic crises are less frequently provoked.

WITH REGARD TO ITS CONNEXION WITH THE DOG AND THE BUG (CONORRHINUS).

BY C. DONOVAN, M.D., B.CH. R.U.I., MAJOR, INDIAN MEDICAL SERVICE.

NICOLLE, of the Pasteur Institute, Tunis, has made out a strong case concerning the association of infantile kala-azar and the dogs of his neighbourhood. He examined the deadbodies of 222 dogs and found four infected with leishmaniosis, a fairly large percentage. At my request Nicolle very kindly sent me a slide of the splenic smear of his dog No. 1; in this preparation I have been able to confirm the presence of leishmania; it is true the parasites are very sparsely distributed in the film, but there is no doubt of their identity.

I have carried out the examination of the splenic smears of the stray dogs destroyed this year in the limits of the corporation of Madras; the investigation began on May 12th, and up to August 14th 1150 dogs have been carefully examined for the presence of leishmania in their spleens, but none out of this large number contained anything similar to the parasite sought for. The dogs were obtained from within the limits of the city of Madras, and 256 of the number were from Georgetown, our endemic area for kalazar.

The dogs were destroyed in a lethal chamber by means of CO₂ gas, and a few minutes after death their abdomens were opened, the spleen exposed, and a smear taken, so the preparations examined by me were very fresh and virtually as good as splenic smears obtained intra vitam. The only parasites found were the so-called leucocytozoon of the dog; 94 out of the 1150 were infected by this organism, a percentage of 8·17. There were no certain evidences of piroplasma (babesia) or trypanosoma infection.

Nicolle has also succeeded in inoculating dogs with his Leishmania infantum; I have tried the same experiment with L. donovani in two instances, but have not met with success.

Dog No. 1, marked "Alpha," a bitch, aged about 4 months, healthy but for the presence of the so-called Leucocytozoon canis in her peripheral blood, was inoculated intrahepatically on the evening of July 10th with 1.5 cubic centimetres of blood removed by exploratory syringe from the spleen of kala-azar patient No. 23 of 1909, who was in a moribund condition. The lapse of time between taking blood from the spleen of the human subject and inoculation into the dog did not exceed half a minute. The animal was destroyed on the evening of August 4th, 23 days after inoculation, as it showed signs of dumb rabies. No leishmania was found in smears of the spleen, liver, or lungs; the preparations of these organs were made immediately after death.

the spieen, liver, or lungs; the preparations of these organs—were made immediately after death.

Dog No. 2, marked "Beta," a young bitch about 7 or 8 months old, healthy, was inoculated on the morning of July 12th, similarly as dog No. 1, from kala-azar case No. 17 of 1909, moribund. This dog, too, developed signs of dumb rabies on August 2nd, 21 days after inoculation; she was chloroformed the same day and a liver puncture was made while under the influence of the anæsthetic; she was then destroyed. The blood taken by liver puncture intra vitam contained no leishmania, neither did the smears of the spleen and liver, made immediately after death, show any evidence of the existence of the parasite.

Patton has previously carried out in Madras similar experiments on three dogs with negative results.

I have recently suspected a reduviid bug (Conorrhinus rubrofasciatus, de Geer) as having some relationship with the causation of kala-azar in Madras; in other words, as being a possible transmitter of the disease. My endeavours in procuring the pullulation of Leishmania donovani in its guts have not so far succeeded. I give here an extract from my paper in the Annual Report of the Government General Hospital, Madras, for 1908:—

The insect in question is a black and red bug (Conorrhinus rubro-fasciatus) of large dimensions, about 20 to 25 millimetres—or roughly

DR. PETER PATERSON: TWO RARE SURGICAL CONDITIONS.

speaking, about an inch in length; it comes occasionally to the light of a lamp into rooms at nights, and appears to be widely spread in Madras. It is popularly supposed to suck the blood of human beings, and also to feed on the common bed bug; from its latter propensity it is called, according to some of my informants, the "mother of bugs," on account, I suppose, of her unmatronly habit of devouring her smaller relations. This predatory habit on bed bugs is also attributed to its European representative, Reduvius personatus; so a certain amount of credence is to be placed on one of the above popular statements of its habits. Both the male and female insects I have captured contained either fresh or digested mammalian blood in their guts, whether human or not I regret I am unable at present to determine, but hope to procure the opinion of a bacteriologist at some subsequent date. These bugs readily suck human blood when placed, confined in either a glass-bottom box or test-tube, on the body of a person; they insert their proboscis and begin to suck as if to the manner born. Both the male and female imagines suck human blood, but the nymphs are much more bloodthirsty, starting to insert speaking, about an inch in length; it comes occasionally to the light of blood when placed, confined in either a glass-bottom box or test-tube, on the body of a person; they insert their probects and begin to suck as if to the manner born. Both the male and female imagines suck human blood, but the nymphs are much more bloodthirsty, starting to insert their proboscis immediately they are placed on a patient, while the adults take a minute and more before they settle down to a meal. In the gut of the adult insects in nearly 30 per cent. large numbers of flagellates of the genus Crithidia are found but no Herpetomonas. This reduvild bug has a wide distribution both in and out of India. Distant in the Fauna of British India Series, Rhynchota, Volume II., page 286, gives the following habits: Sylhet. Bombay, Borghat, Calcutta and Mysore, Ceylon, Andaman Islands, Burma, Toungoo and Mandalay. Outside India it is widely spread throughout the Malayan Peninsula and Archipelago; recorded from Madagascar, West Africa, and generally found in the Southern Nearctic and Northern Neotropical regions and in the Antilles. As mentioned before, this insect's habits are nocturnal; both the male and female, the former more frequently, fly into the verandah or room attracted by light. It is found all the year round, and I have procured specimens from all parts of the city of Madras. A strange and interesting coincidence is Darwin's account of a species of the same genus, found in the Pampas district in South America; I quote from his "Voyage of the Beagle" (page 330 of the 1873 edition). "We slept in the village of Luxam, which is a small place surrounded by gardens, and forms the most southern cultivated district in the Province of Mendoza; it is five leagues south of the capital. At night I experienced an attack (for it deserves no less a name) of the Benchuca, a species of Reduvius, the great black bug of the Pampas. It is most disgusting to feel soft wingless insects, about an inch long, crawling over one's body. Before sucking they are quite thin, but afterwards they become round and bloated with blo

I have had recent proof of this bug feeding voluntarily on human blood. A medical student of mine, named S brought me a nymph of this insect, of about three months growth, on July 30th. The story he related was: "At about 3.30 P.M. on July 29th, 1909, while just waking up trom sleep, I felt something like ants biting me on the leg. When I got up I searched for the ants; I saw a nymph of the Conorrhinus running away from the spot." The insect was full of blood; to make sure of the nature of the gut contents, I despatched the nymph the same day to Major W. D. Sutherland, I.M.S., Medical College, Calcutta, for the favour of his opinion as to whether the blood contained in the gut of the bug was human or not. I received a reply from Major Sutherland on August 6th to this effect: "I crushed the bug at 2 P.M. yesterday (August 3rd)-i.e., 119 hours after the alleged bite. On preparing an extract with 0 85 per cent. NaCl solution and testing this with antihuman fowl serum of known activity and specificity I obtained an immediate and copious reaction. No action with anticanine serum. No ruminant reaction. So we may take it that the nymph had bitten man alone at her last meal at all events." On August 5th I sent Major Sutherland three male imagines of the bug; the results were negative; another male imago on August 13th gave similar results. I am continuing to encroach on Major Sutherland's kindness, and have quite recently sent him the gut contents of a female imago full of fresh mammalian blood, and expect to receive a positive pronouncement this time.

The interest centring round this reduviid bug is the coincidence of the find in Brazil by Chagas of an insect of the same genus transmitting trypanosoma to human beings. It is true Chagas's statements are astounding; time

will, however, clear any doubts that at present exist on his discovery. As mentioned in the excerpt of my report of the General Hospital for 1908, Conorrhinus rubrofasciatus, to the extent of 90 per cent., harbours the flagellate, crithidia. Could Chagas have mistaken these parasites for trypanosoma? It may be mentioned, en passant, that the figures given by Kleine' in the Deutsche Medizinische Wochenschrift, as the developmental forms of T. gambiense, are identical with those of the crithidia found in the proventriculus and stomach of Conorrhinus rubrofasciatus. There appears to be no limit to the existence of the parasitic flagellates in animal organisms, but what is more astonishing and subversive of previously held views is the occurrence of these parasites in the latex or milky juice of plants. Lafont has recently found herpetomonas (leptomonas) in the latex of Euphorbia pilulifera in Mauritius. I have confirmed his find and have discovered these flagellates, small narrow forms, in the latex of the same plants grow-The organisms differ from the known ing in Madras. flagellates parasitic on animals and will doubtless be placed in a new genus, for which I suggest the name of Phytomonas. Madras.

TWO RARE SURGICAL CONDITIONS:

(1) A CASE OF ACUTE TORSION OF THE SPLENIC PEDICLE: RECOVERY AFTER SPLENECTOMY; AND (2) A CASE OF FLOATING LIVER CURED BY OPERATION.

BY PETER PATERSON, M.B., C.M. GLASG., SURGEON TO THE GLASGOW ROYAL INFIRMARY.

IN THE LANCET of Sept. 25th, 1909, p. 917, Dr. Ian Macdonald and Dr. W. A. Mackay of Huelva report a case of acute torsion of the pedicle of the spleen in which they had the satisfaction of saving their patient after removing the strangulated viscus. They also draw attention to the fact that this accident is practically never diagnosed, a circumstance due, probably, to the rarity of its occurrence. If this be the explanation, then the more frequently cases are reported the less likelihood is there of the existence of the condition being overlooked when it does occur; hence the reason for wishing to put on record the following case.

(1) The majority of the cases that have been published have occurred in women who have been pregnant or in whom the organ has become enlarged from malaria, but the subject of this notice was a nulliparous girl, aged 16 years, in whom there was no suspicion of malaria. For five months previous to her admission to hospital she suffered from frequent, almost daily, attacks of abdominal pains of a colicky nature. These pains were localised to the lower part of the abdomen and were never accompanied with vomiting. They were most severe when she lay flat on her back, and were relieved by sitting up in bed. The day before she came under observation the pain became very severe and, for the first time, was accompanied with almost constant vomiting of bilestained fluid. The pain extended across the abdomen from one iliac crest to the other, never altered its position, and, like the previous less severe attacks, was relieved by sitting

up. Flatus was being passed fairly freely.

Examination revealed the presence of a smooth, rounded tumour extending from one iliac fossa to the other, and from the umbilicus to 1 inch above the symphysis in another. It was very firm to the touch, very tender, and practically fixed. Neither rectal nor vaginal examination revealed anything abnormal. The temperature was 103° F., and the pulse was 120. The white blood cells gave a count of 10,000 per cubic millimetre, of which 79 per cent. were polymorphs and 4 per cent. lymphocytes. The red cells polymorphs and 4 per cent. lymphocytes. numbered 5,440,000 per cubic millimetre.

When the abdomen was opened below the umbilicus the mass, which was slightly adherent to the anterior abdominal wall, was found to consist of a greatly enlarged spleen with adhering intestine and omentum. The pedicle had undergone four complete turns, and the vessels, which were about the diameter of the index finger, were completely thrombosed.

Chagas: Neue Trypanosomen, Archiv für Schiffs- und Tropen-Hygiene, Februar, 1909, pp. 120-122; and Über ein neue Trypano-somiasis des Menschen, Ibid., Juni, 1909, pp. 351-353.

 ⁴ Kleine: Weitere Untersuchungen über die Aetiologie der Schlafkrankheit, Deutsche Medizinische Wochenschrift, Jahrgang 35, pp. 1257-1260.
 5 Lafont: Sur la Présence d'un Parasite de la Classe des Flagellés dans le Latex de l'Euphorbia plulifera, Comptes Rendus de la Société de Biologie, tome lxvi., p. 1011.

An incision made into the substance of the spleen did not bleed. The adhesions were separated; the pedicle was ligated, the organ was removed, and the abdomen was closed without drainage. Within the next four days the temperature had fallen to normal and the general condition was satisfactory, but she then developed a severe attack of bronchitis, the temperature registering 104°. For five days the patient was acutely ill, but the symptoms gradually subsided and the remainder of her residence in hospital was uneventful. Three weeks after operation the red blood cells had fallen to 4,320,000, while the white cells were practically stationary, though the lymphocytes had risen to 10 per cent. The observation made by several writers that the appetite is greatly increased after splenectomy was not confirmed in this case. The spleen after removal weighed 324 ounces.

(2) Possibly even a rarer condition than wandering spleen is that in which the liver has become displaced from its normal position. One such case has come under my observation. In December of last year the patient presented herself with the usual symptoms of a floating kidney, and on palpation the right kidney could be distinctly felt near the umbilicus. The viscus was fixed to the posterior abdominal wall through a lumbar incision, and at the time of operation it was remarked that the liver extended somewhat lower than usual. Four months later she returned complaining of a severe dragging pain in the right side. The pain, which extended through to the lumbar region, was relieved when recumbent and aggravated when in the erect posture. There was neither jaundice nor ascites; the appetite was good and meals had no effect on the pain. The bowels were regular. The patient, who was engaged in housework, was well nourished but not stout. She had never been pregnant and the abdomen was neither lax nor protuberant. On examination the liver dulness was found to extend from 1 inch above the costal margin down to the right iliac crest. The under surface looked to the left and slightly downwards, so that besides being displaced downwards it was rotated on its antero-posterior axis. Palpation did not cause pain. Glénard's symptom of retraction of the umbilicus, from traction on the falciform ligament, was absent.

The abdomen was opened by a vertical incision through the right rectus. On passing the hand into the peritoneal cavity the liver could now be easily rotated into position. With a gauze sponge the posterior and upper surfaces of the right lobe and also the under surface of the right side of the diaphragm were vigorously rubbed so as to raw the surfaces slightly and thus permit of adhesions forming between the two when the organ lay in position. The anterior surface of the liver near its lower margin was next fixed to the anterior abdominal wall close to the costal margin by four stout catgut sutures, each suture passing through the abdominal wall on one side of the incision, then well into the liver substance, and out through the abdominal wall on the other side of the wound. When all the four had been passed they were tied, but not so tightly as to cut through the friable liver tissue. The skin wound was closed by a separate continuous suture. The patient was dismissed three weeks after the operation feeling well. When seen four months later the liver was found in position and she was able to perform her household duties without any discomfort.

In this particular case it seems to me that Depage's operation of excising a portion of the abdominal wall so as to increase the intra-abdominal pressure and thus keep the liver in position would have been useless, as the walls were neither relaxed nor unduly prominent. I also fail to understand how increased intra-abdominal pressure can prevent a heavy organ like the liver from sinking towards the pelvis once its attachments have become stretched, as the liver could easily slip downwards and the intestines pass upwards without any increase in the capacity of the abdomen being necessary.

Glasgow.

Donations and Bequests.—Over £500 have been already subscribed in response to the appeal of the committee of the South Devon and East Cornwall Hospital for increased financial support, in order to repay the debt of £3500 which exists against the institution.—The late Mrs. M. L. Toby of Exeter has bequeathed £300 to the Devon and Exeter Hospital and £200 each to the Exeter Dispensary and the Exeter Eye Infirmary.

Clinical Hotes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SPORADIC ELEPHANTIASIS.

BY HUGH BARBER, M.D. LOND., HONORARY PATHOLOGIST TO THE DERBYSHIRE BOYAL INFIRMARY.

THE patient is a widow, 65 years old, who keeps house for her sons; she has lived in Derby for the last 30 years and has never been abroad. She has had three children, the youngest being 30 years old. There is nothing exceptional in the family history. As to previous diseases, she enjoyed very good health until four years ago; at that time she had an attack of sickness and diarrhea, with pains in the abdomen, which lasted about a week. Since that time she has suffered from two attacks of biliary colic, followed by jaundice. Concerning the present disease, about eight months ago the legs began to swell; they became painful, especially after standing; they felt stiff and heavy, and there were cramp-like pains at night. The swelling was noticed before any pain or tenderness developed. During the first few weeks that the legs were swollen she had several attacks of vomiting, sometimes felt faint, and says she felt "lightheaded" at times. She had no shivering attacks and was

not confined to bed.

On examination on June 2nd, 1909, the following record was made: "The patient is a tall, stout woman, weighing about 13 stones. The heart and lungs are healthy. The abdomen is covered with 2 inches of fat; there are no signs of ascites or other abnormality. No pelvic tumour is revealed by vaginal or rectal examination. There are no enlarged by vaginal or rectal examination. lymphatic glands. The legs are much swollen, chiefly from the knees to a point just above the ankles. The right calf measures 17 inches in circumference and the left 19 inches. The swelling does not pit on pressure, it is uniformly firm, and the skin over it cannot be taken up between the finger and thumb. There is some brownish pigmentation, sweating is deficient, sensation is somewhat numbed, and there are small venules visible, and a few knots of varicose veins. The swelling ceases abruptly at the ankle-joints: the skin and subcutaneous tissues of the feet and toes are quite normal. Above the knees tortuous dilated lymphatic vessels, of about the size of a goose quill, can be felt under the skin; they are rather tender at times. The tenderness, both in this situation and lower down, is very variable, and frequently much more marked in one leg than the other. The breasts and external marked in one leg than the other. The breasts and external genitals are normal. The urine has on no occasion contained chyle or other abnormality. Examination of the blood reveals nothing abnormal; the red corpuscles and hæmoglobin are both about 90 per cent. There is no leucocytosis; a differential count shows 60 per cent. polymorphonuclear cells and 30 per cent. lymphocytes; there is no eosinophilia.'

As regards the course of the case, the patient has been under observation for two months, in which time there has been very little change; at times the legs are very tender, at others not at all so. There have been no symptoms of fever. The temperature, taken rather irregularly, has not been above normal. Elastic bandages and massage have much improved her walking powers, she has less pain at night, and thinks the legs are less hard, but they are no smaller.

Remarks.—This case can hardly be said to add anything to the etiology of elephantiasis, which, in sporadic cases, apart from filarial infection, is somewhat obscure. But the fact that the cause of such elephantiasis is not easily explained may make the case worthy of record. There is no evidence of a pelvic tumour or of disease of any lymphatic glands. Recurrent attacks of an inflammatory nature in the lymphatics, which explain some of these cases, usually give rise to much pain and to fairly pronounced constitutional symptoms. In this case the swelling preceded any pain, and although there were some constitutional symptoms, they were slight and did not interfere with the patient's housework. I have twice examined the blood at night for filarial parasites with negative result. The complete absence of

disease in the feet, the most striking feature when one looks at the legs, is unusual, I believe.

Derby.

SIMULTANEOUS FRACTURE OF THE PATELLÆ.

By H. Betham Robinson, M.S. Lond., F.R.C.S. Eng.,

SURGEON TO ST. THOMAS'S HOSPITAL.

In the last issue of THE LANCET Mr. William Sheen describes a case of this injury and draws attention to the rarity of its occurrence. The following case will be found to bear upon the paper just mentioned.

A woman, aged 30 years, who had met with this accident, was admitted under my care into St. Thomas's Hospital in November, 1903. She was walking (or running) downstairs with a tray in her hands when she slipped down about three stairs; she fell forwards and was "quite sure she did not fall on her knees," but tried "to throw herself back." There was no sign of any local bruising over the knees as might be due to a direct blow. Both patellæ were fractured transversely, the right at the junction of the upper and middle thirds and the left across the middle. There was fluid (blood) in both knees. On the sixth day both patellæ were wired and she made an uninterrupted recovery with firm union.

In this case the fractures apparently were due to indirect violence.

Upper Wimpole-street, W.

A NOTE ON A CASE OF INFLUENZA WITH MARKED CEREBRAL SYMPTOMS.

By H. V. McMahon Dillon, L.R.C.S. Irel., L.R.C.P. Irel., L.M.,

LATE DEMONSTRATOR OF ANATOMY, CATHOLIC UNIVERSITY, DUBLIN.

I was called to see a young man, aged 20 years, at 8 A.M. on Feb. 15th, 1908. I found him lying on his bed in a semiconscious condition, unable to be roused; the teeth were tightly clenched, the face was cyanotic, and the breathing was stertorous and accompanied by groaning. The heart's action was fast, tumultuous, and occasionally intermitting, the pulse being 100 per minute, wanting in tone, small, and also intermitting. The pupils were irregular but dilated. He was capable of being roused temporarily by being spoken to in a loud tone of voice; the temperature was 101° F. I was informed that he had risen earlier and on walking to the door he felt giddy and so lay down again, and subsequently the symptoms just narrated gradually supervened. He was given the following draught soon after I saw him at 8 A.M.: Aromatic spirit of ammonium, 20 minims; liquor strychninæ, 3 minims; and water, 12 ounces. Soon after this he was removed to hospital. He remained in the same unconscious state till 10 a.m. When spoken to in a loud tone of voice and stimulated by a gentle slap over the bare chest and cheek he was roused temporarily again, and opening his eyes responded incoherently on being questioned, again relapsing to a semi-conscious condition but less marked than at first. He was given another draught similar to the first. He remained in a dreamy condition for the next few days and gradually under treatment regained his usual mental state, said to be generally of a reserved type.

On Feb 18th his face presented a cyanotic and scorbutic condition. His lungs on auscultation revealed slight symptoms of congestion at the bases, the air causing roughened sounds on inspiration and expiration, as is frequently noticed in connexion with cases of influenza. The temperature varied between 101° and 102° for five days, falling occasionally to 97° and rising to normal, as has been noticed in influenza and other microbic diseases, as malarial fevers, when they affect the nerve centres. He was treated with sulphate of quinine, 2½ grains three times a day, and was given an expectorant mixture as follows: Compound tincture of camphor, 3 drachms; carbonate of ammonium, 16 grains; and infusion of senega, 8 ounces. A tablespoonful every fourth hour. An aperient pill with half a grain of podophyllin resin added was given as required. The diet consisted at first of lemco daily; later, as he became able to take them, he had milk puddings and fish, and on the temperature becoming normal he was placed on solid meat diet. He received no stimulants. He was allowed to sit up on the seventh day, and left for change

of air on Feb. 25th, ten days after the first onset of symptoms, although he was still in a weak condition.

The unusual cerebral symptoms in this case make it probably worth recording. The patient had complained prior to these of slight coryza simulating an ordinary cold. His cyanotic condition was congenital, as was also the irregularity of the heart's action, and he was a subject whom the invasion of microbic disease would be likely to affect more seriously than another having greater resisting power constitutionally.

THE TREATMENT OF GONORRHEAL RHEUMATISM WITH A VACCINE.

BY J. McOscar, L.R.C.P. LOND., M.R.C.S. ENG.

THE treatment of various diseases with vaccines being now fully recognised by the profession the following case may be of interest.

On August 6th, 1908, a young patient was sent to me suffering from gonorrhoeal rheumatism. His trouble was contracted the previous June, and from that time he had suffered with a continuous discharge. For the last month he had been confined to bed with rheumatism. The usual line of treatment had been followed out, salicylates and injections given, with no curative result. I found the third metacarpo-phalangeal joint of his left hand very much swollen and intensely painful; in fact, he was nursing his left hand in a sling with his right. The same evening when he had retired to bed I injected 25 cubic centimetres of antigonococcus vaccine (Burroughs, Wellcome, and Co.) in the mid-scapular region on his left side, using strict aseptic precautions both to the skin and syringe. On my visit the next morning I found he had passed an excellent night with no pain. The site of the injection was showing a slight blush and fulness with a little tenderness on pressure. There was no rise of temperature or constitutional symptoms. I ordered him toget up out of his bed and recommended Dowsing electric light and heat bath as hot as he could bear it for 15 minutes, the joint being previously painted at the bath with liquor iodi fortis by myself. The joint was to be gently massaged by a trained hand afterwards for 15 minutes, no dressings applied, but a sling used. Every second day this was repeated for three baths. On August 10th, or four days following my first interview, the finger was in less pain, and he was able to bend it. On the 14th another 10 cubic centimetres of the vaccine were injected over the same area, the patient being in bed. Fromthe 15th until the 21st the baths and massage were continued every second day, but without any iodine application. On the 22nd the joint could be freely flexed into the palm and all the swelling had disappeared. No other joint was affected; the discharge ceased; treatment was discontinued. He reports himself up to the present time in excellent health.

Remarks.—These cases are as a rule of long duration and difficult to treat successfully—at least, I have always found them so. My patient was under treatment for 16 days, and left in less than three weeks. The vaccine has also proved of great benefit in other cases. Many patients have been treated by me for gonorrheal rheumatism with mineral waters, baths, mineral and electric, and massage, but in no case have I found such gratifying results as when giving vaccine.

Buxton.

BRITISH FIRE PREVENTION COMMITTEE.—The work of the British Fire Prevention Committee for the session that has just commenced includes the preparation and issue of reports in respect to a number of doors and roller shutters that have been recently tested by the committee and will be embodied in five reports. We understand that an elaborate report is also about to be issued by the committee on the flannelette question, which has been the subject of an extensive series of tests comprising some 450 specimens, and that two reports are in preparation on fire extinguishers, including a petrol extinguisher. The tests to be undertaken during the next month include a final series of door tests mainly relating to composite doors, whilst the matter of roofing materials will shortly occupy the attention of the committee.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Nov. 8th, Dr. SAMUEL WEST, the President, being in the chair.

Mr. H. STANSFIELD COLLIER showed eight cases of Congenital Dislocation of the Hip treated by a modifica-tion of Lorenz's operation, and Mr. H. A. T. FAIRBANK showed three cases of Congenital Dislocation of the Hip after Lorenz's operation. The modification in Mr. Collier's method of operating was the pinching of the obturator nerve in the pelvis. This was done a fortnight before replacement was applied, and a weight extension of some 4 pounds was applied so as to stretch the paralysed adductor. Mr. Collier had employed this method 14 or 15 times since October, 1909. He reserved until some future occasion discussion of the considerations which led him to adopt this plan, and confined himself to the expression of a belief that the results were better than he had experienced previously, though he had to regret one case in which he failed to get reduction, and a second case in which the dislocation relapsed, to be successful, however, on the second occasion. He had found that the amount of violence necessary for reduction was much less, and that shock and pain were distinctly less, the amount of hæmorrhage being as a rule inconsiderable.—In the discussion which followed Mr. A. H. Tubby, Mr. E. Owen, and Mr. Charters J. SYMONDS took part, and Mr. Collier and Mr. FAIRBANK

Dr. T. D. SAVILL showed three cases of Spasmodic Tic treated by systematised exercises. The first case was that of a married woman, aged 48 years, who was sent to Dr. Savill by Mr. Henry H. Sturge on account of spasmodic blinking movements of the left eye and other facial muscles, which had existed in greater or less degree for 10 years. The movement had during the past two years spread to the neck, more particularly the left side, movements like a clonic torticollis. The disfiguring grimaces made by the patient prevented her going into society or public places and had latterly been attended by pain in the left supra-orbital region. Dr. Savill started treatment by systematised exercises to the head and neck on May 5th, 1909. The following prescription was also given twice daily for a time: Tr. gelsemii, m 5; liq. arsen. alk., m 3; ammon. brom., gr. x.; soda bicarb., gr. x., t.d.s. She carried out the systematised movements of the head and neck and respiration for 10 minutes at the first three, then four times daily, and finally every two hours. The clonic spasms soon became less pronounced and more under control, and in three months' time (i.e., in August, 1909) all the spasmodic twitchings had completely disappeared. The second case was one of generalised spasmodic tic with marked affection of the respiratory muscles in a female patient, aged 25 years. The clonic muscular twitchings began when she was about 10 years of age, after a fright from a dog. She was admitted under Dr. D. Ferrier into the National Hospital for the Paralysed and Epileptic in 1901 with generalised choreiform movements; they had persisted ever since and prevented her from doing any domestic or other work. From time to time thyroid enlargement had been noticed. The movements involved the upper extremities and she was continually attempting to smooth her hair back from her face. The head was affected with violent nutatory spasms, and the twitchings of the respiratory muscles produced recurrent gruntings. She was admitted to the West-End Hospital for Diseases of the Nervous System in February, 1907, where she was put upon systematised respiratory exercises and arm movements. At the end of two months the improvement was sufficient to enable her to bandle cups and saucers, and at the end of four months (May, 1907) the matron took her into the service of the hospital as a cleaner. No other treatment excepting exercises and purgatives was adopted. All her life she had been constipated. The twichings still persisted but only in a very slight degree, so that the patient was able now to take a situation as a domestic servant. In the third case the patient was a male, aged 18 years. The spasmodic jerky movements dated from a fright when he was six

Three days after his head began to shake vears old. spasmodically. The spasmodic movements gradually spread to the arms and thorax. He had attended the National Hospital and many other hospitals without relief. Whilst in the London Hospital he had to be put in an isolation ward because of the loud grunting and barking noises produced by his respiratory jerks. On Feb. 1st, 1909, he was started on a course of respiratory and sys-tematised exercises, which had been continued more or less up to the end of August, but without any appreciable effect. Dr. Savill said that all the three cases belonged to the same class of disease, clonic coördinate muscular spasms more or less beyond the control of the will. A very strenuous effort of will could control the movements for a short time only. Trousseau suggested gymnastic exercises for spasmodic tic (non-douloureux). Between 10 and 15 years ago, when Dr. Savill was honorary physician to the People's Palace Gymnasium and Polytechnic Gymnasium, he met with numerous cases of spasmodic tic among the pupils, and it occurred to him that if he could induce such patients to bend their attention steadfastly on normal systematised movements of the affected muscles, regularly and sufficiently often, the unstable paths and powers of inhibition would be re-educated. In nearly every case where the patient was able to give sufficient time and attention cure resulted. About five years ago Henry Meige contributed his classical lectures advocating the same procedure. The pathology of these spasmodic tics appeared to him to be fairly simple. Briefly, it consisted of an explosive motor impulse along a too well-beaten nerve track. The principle on which the treatment depended was the replacement of these explosive morbid movements by slow, rhythmical, systematic healthy movements of the same muscles at frequent intervals during the day, the patient's attention being fixed steadfastly on these movements. Some cases were incurable, but the recovery in Dr. Savill's first case and the improvement in the second case were striking. About three-fourths of his cases had improved. Dr. Savill noted that three of the cases of spasmodic tic which he had seen during the past 12 months presented, or had previously presented, thyroid enlargement.-Dr. L. G. GUTHRIE said that when "tics" became purely habitual exercises were of use, and Dr. SAVILL, in the course of his reply, agreed that in the early stages of "tics" exercises were of little use; it was necessary to wait till the "tic" had become habitual.

Dr. F. S. PALMER and Mr. C. A. BALLANCE showed a case of Traumatic Epilepsy successfully treated by operation.

Mr. W. H. CLAYTON-GREENE showed a case of Laryngectomy for Endothelioma. At the operation it was found
that the growth had spread into the pharynx and upper end
of the œsophagus, necessitating the removal of the whole
pharyngeal wall and the upper half inch of the œsophagus.
The wound was packed, a tube being sewn into the cut end
of the œsophagus. Later a Symonds's tube, still worn, was
introduced through the mouth. The operation was performed in March of this year; there were no complications.
Since then the patient had put on weight and only complained of a little local trouble just about the treacheal
wound, probably due to a deep ligature.

Dr. W. ESSEX WYNTER and Mr. T. H. KELLOCK showed

Dr. W. ESSEX WYNTER and Mr. T. H. KELLOCK showed a case of Osteitis Deformans in a married woman, aged 42 years, who eight years ago began to suffer pain in the ankles and legs after standing. Four years ago the patient first noticed the deformity of the left leg, the left femur being much thickened and bowed forward. The right femur was similarly affected to a less degree. The tibiæ were somewhat concave on the internal surface. A skiagram of the left femur showed the bone to be enlarged in all dimensions, and the shadow cast by it was abnormally dark.

Mr. V. WARREN Low showed a case of Abdominal Hydatids, the patient being a man who was shown before the society by Dr. Bertrand Dawson on Nov. 9th, 1903.

Dr. J. Walter Carr showed a boy, aged 15 years, described as a doubtful case of Cerebral Tumour. Dr. Carr pointed out that the exact position and nature of the tumour were quite uncertain, but the fact that the patient had remained without symptoms since January, 1908, until the end of last September, when the patient was readmitted to hospital on account of a rather sudden return of symptoms, suggested that it was probably tuberculous.

Dr. F. S. LANGMEAD showed two cases: the first was one

of Rheumatoid Arthritis in a boy the subject of polyarthritis, the wrists, knees, ankles, elbows, and many of the smaller joints of the fingers showing the characteristic spindle-shaped enlargement without evidence of being overgrowth. The tendons were commencing to contract, causing slight deformity and a stooping, shuffling gait. Dr. Langmead observed that treatment with iodide of potassium and guaiacol carbonate was certainly producing slow improvement. His second case was that of a boy showing Congenital Malformation of the Arms. These limbs were greatly shortened, due chiefly to suppression of the radius and ulna on each side. There were only two digits on the right side and one on the left.

Dr. WILFRED HARRIS showed a case of Chronic Syphilitic Poliomyelitis in a woman.

Mr. E. M. CORNER showed a case of Pott's Fracture 15 months after treatment by operation.

OPHTHALMOLOGICAL SOCIETY.

Measurement of the Desire for Binooular Vision .- Exhibition of Cases and Specimens .- Oxycephaly.

A MEETING of this society was held on Nov. 11th, Dr. G. A.

BERRY, the President, being in the chair. Mr. N. BISHOP HARMAN read a paper on the Measurement of the Desire for Binocular Vision by means of the Diaphragm Test. He said that individuals showed variation in the sensibility of their cerebral functions. Colour and light sense, smell, taste, and hearing all varied, and the muscle sense that maintained body balance no less. There were extremes of mental defect and striking endowment, but within the socalled average capability there was also a wide range of variation. So far the capability for binocular vision had escaped a similar critical study. Our tests either determined the presence or absence of binocular vision, or were complicated—as in the use of prisms and stereoscopes—by muscle stresses which vitiated the results. The diaphragm test was a pure test for binocular vision, and by a variation of its mode of application it was possible to measure the desire for binocular vision as easily as the stature or weight of a man could be ascertained. The test-cards seen through the hole in the screen of the test were viewed for their greater part by each eye separately, but a median band was seen by the direct vision of the two eyes together; this median band acted as a balancer to the eyes and their controlling mechanism; for this reason it was called the "ocular poise." Experiments showed that different individuals, and the same individual under different conditions, required different breadths of ocular poise, the more perfect the binocular vision the narrower the ocular poise required to maintain the eve balance; hence the smallest measure of the ocular poise became the measure of the desire for binocular vision. The standard pattern diaphragm test had a fixed hole in the screen of 17 millimetres; the instrument to measure the ocular poise had a variable aperture. The aperture was varied by means of shutters which were moved by suitable gearings; the variation of the ocular poise was shown automatically upon a scale. The scale had a compensating adjustment for the varying width between the eyes of different subjects, so that the measures given by the test became truly comparative. Examination of binocular vision by this means showed how essentially cerebral was the controlling mechanism of the eyes, how greatly it varied in different individuals, and how profoundly it was affected by conditions of ill-health and fatigue. There seemed little doubt that on these points the test opened up many possible fields for physiological and psychological inquiry. To the ophthalmic surgeon the new test had a particular value for those cases of occasional divergent squint with feeble convergence which were due to defective cerebral control. These were those for which at present we had been able to do but very little. With the variable aperture to the diaphragm test the ocular poise could be made so large as to present an attractive point of binocular fixation; and with practice control of the eyes might be developed, so that the balance could be maintained under conditions of gradually increasing difficulty.

Mr. Sydney Stephenson showed a case of Pigment on

rare type of persistent capsulo-pupillary membrane. PRESIDENT agreed with Mr. Stephenson's views.

Dr. RAYNER D. BATTEN exhibited and demonstrated an Instrument for the Examination of the Eye Under Water in the Erect Position, and showed its applications as a means of treatment. In glaucoma, for instance, after removing the instrument the haze of the cornea disappeared. He had not had any untoward incidents with it.

Mr. E. A. DORRELL showed a case of Choroidal Degeneration.

Mr. W. M. BEAUMONT read a paper on Oxycephaly, illustrated by a number of lantern slides. He did not agree with Patry in considering that the term "syndrome" should be applied to the association of oxycephaly with optic neuritis or atrophy, as the nerve involvement was secondary result which might or might not follow. Very considerable interest had been taken in the disease in recent years since the articles by de Michel and A number of cases had been recorded in the United Kingdom, but he thought that the credit of first pointing out the clinical symptoms of oxycephaly was due to Wm. Mackenzie of Glasgow. His description had strangely failed to attract the attention which it deserved. This keen observer had noted the shallowness of the orbits and the consequent exophthalmos; the vertical position of the roof of the orbits, the extreme height of the head, and the blindness. Mr. Beaumont drew attention to the excess of males over females: in 14 cases recorded in recent British literature there were 5 females. In Patry's list, drawn from French and German sources, there were 7 females in 64 cases. Mr. Beaumont disagreed with Dorfmann, who advocated trephining to prevent optic atrophy, because he considered that the optic neuritis and atrophy were not due to an increase of the intracranial pressure, but were rather the result of direct injury by bony distortion. Patry had stated that Sir Walter Scott and others had suffered from a slight degree of this disease. If this were true, it was possible that cases of arrested oxycephaly might be overlooked, and he threw out the suggestion that possibly sometimes so-called idiopathic optic atrophy might be due to a fruste form of oxycephaly.—Mr. BISHOP HARMAN said he had met with six cases in the London County Council blind schools and had found Mr. Beaumont's statement true that they were not as a rule mentally defective. -Mr. Stephenson recalled a case, which was exhibited by Dr. James Taylor before the Society for the Study of Disease in Children, which had occipital meningocele and optic atrophy.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

The Care and Training of the Feeble-minded. - Mongulian Idiocy.

THE autumn meeting of the Northern and Midland division of this association was held at the Royal Albert Asylum for the Feeble-minded, Lancaster, on Oct. 21st, Mr. A. R. DOUGLAS, the medical superintendent, being in the chair.

Mr. Douglas read a paper entitled "The Care and Training of the Feeble-minded." He gave a short outline of the history of the treatment of the feeble-minded, pointing out that the first to appreciate the condition of the imbecile was Dr. Itard of the Bicêtre in Paris, and that at a later date schools were formed in England, Germany, and Switzerland, and afterwards in America and Scotland. These were all due to private charitable enterprise, and though brilliant results were obtained in them in many cases, the possibilities of the education of the idiot were somewhat overestimated. Mr. Douglas then said that the care and protection of the children ought to be the first consideration, special attention being paid to their hygienic surroundings and to their condition of health. An important factor was the bringing of the idiot into the society of those who were his equals, which stimulated a healthy condition of rivalry amongst them. The control and discipline of life in an institution also had a beneficial effect on them, tending to encourage industry, honesty, and self-respect. He next gave a sketch of the methods adopted at the Royal Albert Asylum with its various schools and workshops, where in the first place an attempt was made to cultivate the senses, to perfect the the Anterior Capsule of each Lens, probably representing a faculty of muscular coordination, and to establish normal relations between the brain and the hand. This was followed by the more serious problem of learning to read and write, a problem which was, of course, attempted in selected cases only. He then gave a description of what was probably the most interesting part of the institution—namely, the Herbert Storey Industrial Schools and Workshops. In these departments boys were trained in carpentry and wood-carving, the making of clothes, boots and shoes, baskets, mats, &c., as well as in bookbinding, printing, and other occupations. The estate also provided work in the gardens and on the farm for lads who showed an aptitude for it. He concluded a most interesting paper by asking the question: "Besides training and educating these obviously defective children, are we doing anything for future generations?" and had to answer it by saying, "We are not."—Some discussion followed, in which Dr. S. A. GILL, Dr. THOMAS W. McDowall, and Dr. Bedford Pierce took part.

Dr. D. Hunter had prepared a paper on Mongolian Idiocy, the reading of which was prevented by the time limit. He showed, however, a series of photographs illustrative of the condition. His conclusions briefly were: that Mongolian idiocy was not an entity, that all the characteristics of the condition could be paralleled in the fœtus, and that in short the Mongolian idiot was a grown-up fœtus. He also demonstrated some morphological aspects of the Mongolian idiot, suggesting that the orang-utang possibly approached much nearer to the line of human ancestry than did either the gorilla or the chimpanzee.—Dr. R. G. Rows made some remarks with reference to the photographs of brains shown by Dr. Hunter.

The meeting was brought to a close by an adjournment to the Winmarleigh Hall in the Asylum, where the Right Hon. Lord Muncaster unveiled a memorial window in memory of the late Sir John Hibbert.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Scopolamine-Morphine Anæsthesia.

AT the opening meeting of the eighty-ninth session of this society, held on Nov. 3rd under the presidency of Dr. BYROM BRAMWELL, as we have already reported,

Dr. H. TORRANCE THOMSON and Dr. DENIS COTTERILL contributed a paper on the Use of a Combination of Scopol-amine and Morphine as an Anæsthetic Adjunct. They had employed two different methods: 1. The administration two hours previous to operation of 1-64 grain of scopolamine bromohydrate with 1-6 grain of morphia sulphate. In the majority of the 34 cases in which this method was tried induction of anæsthesia was by chloroform, and was maintained by ether given by the open method. This method had been strongly recommended by Dr. Rouffart and Dr. Walravens of Brussels at the International Surgical Congress of 1908. 2. Three preliminary doses of the scopolamine-morphine combination were given at intervals, the first dose two and a half hours, the second one and a half hours, and the third half an hour before the operation. From 1-120 to 1-100 grain of scopolamine with 1-8 gr. morphine was the usual amount of each dose. The effects of the two methods differed only in degree, and were more pronounced in the latter than in the former method. Dr. Thomson and Dr. Cotterill had employed these methods in about 150 cases. The advantage of the combination was, roughly speaking, based on the associated hypnotic and anæsthetic properties of the alkaloids and on their toxic effects on the respiration and circulation being antagonistic and therefore counterbalancing each other. Attention was drawn to the fact that false teeth must be removed before the drugs were injected. Temporary giddiness was complained of when a large dose (1-64 grain) was given, but not when the doses were subdivided and given at intervals. Sleep quickly followed after the first dose, and usually the third dose form were very gradually administered the patient. If chloro-form were very gradually administered the patient did not wake up at all, but if it were administered in strong vapour the patient usually was roused and resisted. In the majority of cases the patient was put sufficiently well by functional disturbances of the nervous system. Emphasis under with considerably less of the ansesthetic than was laid on this point as of the greatest importance.

usual without the scopolamine-morphine injections. Even when a patient awoke during an operation a very few whiffs of the anæsthetic sufficed to produce quiescence. Their practice was to put the patient fairly well under chloroform until the skin incision had been made, and then the mask was removed and only reapplied if the patient showed signs of "coming out." At first they found it somewhat difficult to judge as to when cutaneous sensibility to cutting was abolished, but with experience this was overcome. The corneal reflex was often absent at an early stage of the narcosis and stress could not be laid on this sign. In over 60 per cent. of the cases the pupil previous to the application of the chloroform mask was moderately dilated, but it contracted, as in normal anæsthesia, as the narcosis deepened. After the injections the breathing tended to become slow, and in some cases as low as eight or even six per minute. On the application of chloroform the breathing became slightly irregular and more rapid, but quieted down as in normal sleep as narcosis deepened. In those cases in which the respirations fell to a rate of 12 per minute or lower, the patients maintained a perfectly good colour and seemed in no way embarrassed. The temperature was apparently unaffected. The tendency was for the pulserate to fall and for the tension to remain about the same or to be slightly raised. Slight disturbance of the patient often raised the pulse-rate from 60 or 70 to 100 or over, but this on fell to its normal when the patient fell asleep again.

Dr. Thomson and Dr. Cotterill had not met with any case in which any undesirable effect took place on the circulation, and even in a case of lobar pneumonia, in which operation was performed on the seventh day, the result was eminently satisfactory. The combination had been employed in the cases of several very frail old men and women with equally satisfactory results. The results as regards sickness had been very encouraging, and in the whole series of cases there had not been one case in which sickness was in any way troublesome. There was no case of vomiting on the operating table, and only very occasionally did slight retching take place. After sickness also was conspicuous by its absence and the worst cases were those in which patients vomited three or four times during the evening and night following the operation, but the total number of such cases did not exceed half a dozen. In from 30 to 40 cases the patients brought up one or two mouthfuls of fluid in the evening, but without retching or vomiting, and were perfectly comfortable immediately afterwards. Dr Thomson and Dr. Cotterill had been struck by the absence of nausea, retching, or vomiting either during or after the operation, and the nurses were very decidedly of opinion that the afternoons and evenings of operation were very much quieter than in the days before this combination of drugs was employed. The effects of the drugs varied in different patients. Old frail patients, young patients, patients with poor physique, and the stolid type of patient reacted more markedly, while robust persons and intemperate or nervous persons required larger doses. As a rule, the effect of the drugs was at a height about two hours after administration and the effect lasted five or six hours. Dr. Thomson and Dr. Cotterill had not noted any bad effects, and except in cases where it was necessary to awaken the patient to clear the mouth and nose of blood, there was difficulty in suggesting any contra-indications. They had found chloroform the most satisfactory in inducing anæsthesia on account of the vapour being less irritating than that of ether. Even when patients were apparently sound asleep they nearly always coughed and choked when ether was applied, and this tended to rouse them. When anæsthesia had to be continued during operation there was no difficulty in keeping the patient satisfactorily under with a small amount of ether given on an ordinary Schimmelbusch mask. Summarising, the following conclusions were arrived at:-1. As a result of giving either the single or the three preliminary doses, fear, as a source of danger in the performance of operation, was done away with. Fear predisposed a patient to sudden syncope, and this was accountable to a very great extent for the cases of sudden death which formed so large a proportion of the casualties which took place during chloroform administration. It might also be accepted as proved that emotional shocks were prone in certain patients to leave persistent after-effects manifested by functional disturbances of the nervous system. Emphasis

In the majority of cases the anæsthetic might be administered without waking the patient, and even in hospital, where conditions of quietness were not favourable, a large proportion of the patients had no recollection of having been removed from the ward. 2. That the amount of anæsthetic required was small. The more the combination of drugs was pushed the less was the amount of chloroform or ether required. In nearly half the cases, after the preliminary incision had been made, no further application of the anæsthetic was necessary, and in the remaining cases a whiff of chloroform was only given from time to time during the continuation of the operation, or small quantities of ether were given continuously by the open method. In no case where the anæsthetic pure shock noticeable was removed early in the operation was shock noticeable, even though the operation was a severe one, such as amputation of the foot or leg, but even when larger amounts of the anæsthetic were required, the authors still claimed the advantage of the preliminary injections. 3. Owing to the fact that the drugs inhibit to a great extent the secretion of mucus and saliva, less trouble is experienced during the administration of chloroform or ether. 4. That both during and after operation sickness is much less liable to occur. 5. That the patients continue sleeping for several hours after operation and are thus spared much pain and discomfort. Though Dr. Thomson and Dr. Cotterill had not tested the combination of scopolamine and morphine injections in operations conducted under local or spinal ansesthesia, they were convinced that the mental effect on the patient would be most advantageous.

Professor F. M. CAIRD briefly narrated the various sedatives which had been employed to produce anæsthesia, and stated that the employment of scopolamine and morphine was particularly good in cases of spinal anæsthesia.

Mr. ALEXANDER MILES said that in his experience hyoscine had not proved an innocent drug. When he first employed the method he used large doses, but now 1-100 grain of scopolamine with ½ grain of morphia divided into three injections were given. He found that it took longer to put the patient under the influence of chloroform when these injections had been given because of the slowness of their respirations.

Mr. J. M. COTTERILL said that the use of the injections on the whole gave him a very favourable impression. There were entire absence of alarm on the part of the patient previous to operation and a subsequent calm for many hours after operation, and the patients seemed to suffer less from shock. He employed these injections in almost every case requiring operation.

MEDICC-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 10th, Dr. James Swain, the President, being in the chair.—Dr. J. R. Charles showed a case of Kala-azar from which the parasite had been obtained by hepatic puncture, and a case of Myasthenia Gravis, who, in addition to the usual group of symptoms, suffered from weakness of the bladder sphincter.—Dr. A. Rendle Short referred to the apparent immunity from kalaazar enjoyed by those who in early life were affected by oriental sore.—Dr. Walter C. Swayne read a paper on the Treatment of Retroversion of the Gravid Uterus, describing the difficulties and dangers of neglected cases. Disturbances of micturition were most important symptoms and catheterisation of the distended bladder frequently became no simple matter to be entrusted to a nurse. emptying the bladder digital reposition of the uterus could not be affected, even with the aid of the vulsellum and an anæsthetic, the cervix should be dilated and the uterus emptied. This failing, laparotomy should be performed, when adhesions, the common obstacle to reposition, could be dealt with. He related three cases to illustrate the various methods.-Dr. A. Fells recommended the value of the knee-elbow position as an aid to digital reposition, also the use of a large curved sponge-holder to exert pressure on the fundus. - Mr. D. C. Rayner described a case complicated by the presence of a fibroid in which he performed laparotomy, and on account of hamorrhage on attempting to enucleate the fibroid was compelled to do a complete hysterectomy. The President thought Dr. Swayne too apologetic on behalf of laparotomy; pregnant women bore abdominal operations well, and he suggested that laparotomy was preferable to abortion.-Dr. T. A. Green mentioned a case with persistent vomiting as the chief factor.—Dr. F. H. Edgeworth

showed a case of Recovery from Tuberculous Meningitis. He admitted the diagnosis to be doubtful, but considered that the symptoms of headache, cranial tenderness, vomiting, moderate double optic neuritis, slight fever, and a positive Pirquet's cutaneous reaction were in favour of tubercle; the absence of signs of any other disease, the absence of cells or micro-organisms from the cerebro-spinal fluid, and the relief obtained from spinal puncture supported this diagnosis. - Mr. W. H. Harsant quoted Dr. A. Martin's recent paper which showed the recovery rate in tuberculous meningitis to be about 1 per cent.-Dr. B. M. H. Rogers thought recovery commoner than usually supposed, and said that Pirquet's reaction had proved a reliable sign after prolonged use at the children's hospital. - Dr. R. Waterhouse suggested that the possibilities of anæmia or syphilis had not been quite excluded, and mentioned the occasional success of morphine injections in meningitis. — Dr. Rendle Short read a paper on "Iodoform and Thyroidism" based on a case in which the external application of iodoform to a wound appeared to bring on typical Graves's disease, lasting for 12 months. Iodoform when absorbed was excreted by the thyroid gland as iodothyrin, excessive absorption might produce thyroid intoxication, and in a susceptible person the thyroidism might prove chronic. Children were relatively insusceptible to iodoform intoxication.—Dr. R. Shingleton Smith said he had used iodoform internally in many cases but had seen no results suggestive of thyroidism. - Dr. Rogers corroborated the statement that children were insusceptible to iodoform poisoning. -Dr. L. E. V. Every-Clayton was surprised to hear that fever was a symptom in Dr. Short's case, as he had never heard of a drug which could produce pyrexia. - Dr. Waterhouse was not inclined to accept the suggestion made by Dr. Short that endemic goitre might be due to deficiency of iodine in the drinking water, since recent observations had shown that goitre was prevented by boiling the water.— Fleet-Surgeon W. E. Home, R.N., compared the delay in appearance of toxic symptoms after iodoform absorption with delayed chloroform poisoning. - Dr. P. Watson Williams described the operation he had performed on a patient suffering from Double Fronto-Ethmoidal Sinus Suppuration, showing the patient and a model illustrating the operation.

West London Medico-Chirurgical Society.-A meeting of this society was held on Nov. 5th, Dr. Neville T. Wood, the President, being in the chair.—Dr. P. S. Abraham showed a case of Pemphigus Vegetans of nine weeks duration in a woman aged 42 years. She had good health till ten months ago and gave birth to a child four months The pharynx and larynx were affected, the larynx showing bright redness without ædema. Attempts to cultivate organisms had so far failed. -Dr. Abraham also showed a case of Multiple Lupus in which X rays had failed and in which Mr. E. Reginald Morton was trying the solid CO₂ pencil. It was too early to report the result .--Mr. Walter E. Fry showed a case of enlarged Tibial Tubercles in a boy aged 16 years.—Dr. H. Robinson remarked that the condition was described as "Schlatter's disease." Several members of the society said it was not uncommon to find this condition in young people who played football, and that it persisted in later life as a bony enlargement.— Mr. L. A. Bidwell said he thought there was an inflamed bursa under the tendon in some cases. -Mr. Fry also showed a case of Congenital Scar of the Upper Lip in a child aged 2 years. There was a scar on the left side of the upper lip simulating the result of an operation for hare-lip. No operation had been performed. There was a deformity of the left nostril. There was a family history of hare-lip and cleft palate.—Mr. D. C. L. Fitzwilliams showed a case of Syphilitic Periostitis of the Right Tibia in a boy aged 11 years —Dr. A. E. Saunders showed another case of Syphilitic Periostitis of the Tibiæ in a girl aged 12 years.—Mr. G. Graham showed a patient, aged 25 years, from whom Mr. C. B. Keetley had successfully removed a Ruptured Spleen. The operation was performed six hours after the accident, the abdomen being then full of blood. Now, 14 weeks after the accident, the patient felt well except for some shortness of breath on exertion.—Mr. Cecil H. Leaf showed a patient from whom he had removed the Tongue and Glands of the Neck. He recommended that the operation should be done in three stages: (1) removal of the glands and tying of the lingual artery on one side; (2) the same operation on the other side; and (3) removal of the tongue. He also showed two patients in whom he had excised a portion of the Colon

containing Carcinomatous Growth, with end-to-end anasto-One patient required no purgative to make the bowels act; the other had to take an occasional laxative. Mr. Leaf also showed a boy, aged 11 years, from whom he had removed a Thyroglossal Cyst. He had operated twice on him. The condition was not completely cured, but as only a drop or two of fluid exuded every six or seven days he thought that no further treatment was indicated. - Mr. E. Archibald Smith showed a woman, aged 36 years, the subject of Myxœdema, in whom the left forearm was 14 inches larger in circumference than the right. Under thyroid treatment the arm had diminished half an inch in circumference and was softer. - Mr. Smith also showed a case of Gumma or Epithelioma on a Leukoplakial Tongue in a woman aged 57 years. No definite history of syphilis could be obtained. The microscopical report on a piece excised was The growth had become slightly flatter under doubtful. treatment, but having the opinion of the society he came to the conclusion that it would be better to remove the tongue at once. -Mr. Smith also showed a child, aged 1 year and 10 months, with Six Fingers on each Hand and Six Toes on each Foot. -Mr. Reginald Morton said that from the radiograms he had made there was no doubt that the extra fingers were supernumerary fifths.—Mr. Bishop Harman showed two cases of "Coppock" Cataract. The parents were not related and did not appear to be related to any of the families which had been previously investigated who exhibited this defect. The lenses of both parents were

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Nov. 9th. - Mr. Leonard A. Bidwell, the President, was in the chair, and chose for the subject of his address the Development of Gastric Surgery. He said that the first case of gastric surgery on record occurred in 1602 in Brandenburg, where a knife was removed from the stomach of a sailor by Mathieu, probably, he presumed, after the formation of an abscess. A case was mentioned to exemplify the treatment of 100 years ago in which a penetrating wound of the stomach, occurring in 1784, recovered without surgical treatment, and even after the introduction into the stomach of various fluids, which was, however, afterwards abandoned. In 1808 a record of certain cases of ruptured gastric ulcer showed that they were all fatal and that no operation was even thought of. Gastric surgery was non-existent. The absence of anæsthesia and the belief in the fatal result of all wounds of the peritoneum excluded the suggestion of it. The first operation on the stomach was performed by Sedillot in 1847, but no successful cases were recorded before 1875. Billroth experihuman subject was a pylorectomy by Péan in 1879, and decade 1880-90 was one of great progress: gastro-enterostomy by Wolffer, resection of ulcer by Rydyger, dilatation after gastrostomy by Loretta, gastroctomy by O'Connor, gastro-enterostomy by Van Hacker, and pyloroplasty by Heinhe and Mikulicz. In the next decade occurred the first successful case of operation for perforated ulcer. This was performed by Kreig in 1892. Doyen published accounts of several successful operations for ulcer, but even in 1899 the operation was in this country considered quite unjustifiable, notwithstanding the successful operations of many surgeons. It was not till the present decade that gastric surgery had become actually recognised and popular, and operations, whether for malignant disease or for simple ulcer, were now of everyday occurrence. Removal of the greater part of the stomach in certain cases of malignant disease was found to be quite a desirable operation, affording a hope of radical cure in about 30 per cent. of the cases. In cases where gastric ulcer had recurred after operation gastro-enterostomy was found to have very satisfactory results. In cases of rupture operation was also very successful, the more so the earlier it was performed. In severe hæmorrhage operation was almost always advisable, a catgut ligature being tied round the ulcer to prevent a return of the hæmorrhage. In cases of foreign body in the stomach, tumours, adhesions, &c. operation was the most satisfactory treatment, and was attended with very little risk. The result of the removal of the entire stomach in certain cases had shown that this organ was not so necessary to digestion and life as was formerly supposed.

Indeed, the rapid entry of food into the intestines appeared to have been, in many cases, rather favourable to digestion than otherwise. It was possible, of course, that reaction might set in, that the importance of the stomach in digestion might be more highly estimated, and that surgeons would become more adverse to gastric operations; but, in any case, they had been taught by the experience of the last 20 years that the stomach was an organ well within the reach of modern surgery and that the old-fashioned method of depending on the appearance of the tongue to diagnose the exact condition of the stomach was partial, one-sided, and out of date.

CLINICAL SOCIETY OF NEWCASTLE-UPON-TYNE.

—A meeting of this society was held on Nov. 4th, Mr.

J. W. Leech, the President, being in the chair, and was
devoted to clinical cases and pathological specimens, the
following being shown:—Mr. John Clay: A patient after
Appendicectomy by an American method, with criticism of
modern methods of appendix operations.—Dr. W. E. Hume:
(1) Splenic Anæmia; (2) Locomotor Ataxy to illustrate improvement by Fraenkel's method; and (3) Symmetrical
Atthritis in a child.—Dr. J. S. McCracken showed a series
of Congenital Heart cases.—Mr. T. G. Ouston: (1) Absent
External Auditory Meatus with Malformation of Pinna; and
(2) Congenital Syphilis.—Dr. D. W. Patterson: (1) Pityriasis
Rubra Pilaris; and (2) results of treatment of Rosacea in a
girl aged 17 years.—The President: (1) Esophagotomy for
impacted false teeth; and (2) two cases of Sarcoma of the
Leg following traumatism.—Dr. Horsley Drummond:
(1) Hemiplegia in a child following bullet wound; and (2) a
child with Cirrhosis of the Liver and Enlarged Spleen.—Dr.
H. Glen Davison: (1) specimen from a Purpura case; and
(2) specimen from a Cerebral Hæmorrhage case.

Manchester Medical Society.—A meeting of this society was held on Nov. 3rd, Mr. J. W. Smith being in the chair. - Dr. Eugene S. Yonge, in a communication on a New Method of Treatment for Paroxysmal Rhinorrhœa and Hay Fever, referred to the notorious intractability of these maladies, and described a procedure which he had introduced, and which consisted briefly in the excision of the septal tubercle on both sides, together with the surgical treatment of two other areas in the nasal cavity, which appeared to be also concerned in the production of the characteristic reflex manifestations. A number of severe cases of paroxysmal sneezing, paroxysmal rhinorrhœa, and hay fever had undergone this treatment, and the results had been very satisfactory. The symptoms in all the patients, except one, had either been entirely abolished or so markedly relieved as to cause little or no inconvenience. - Dr. Judson S. Bury gave a communication on Paralysis in Chorea, and Dr. C. H. Melland read a paper on the Treatment of Chlorosis.

SANITATION IN DOLGELLY.—After years of discussion and negotiations Dolgelly urban council (Merioneth) has unanimously decided to instruct an engineer to prepare detailed plan and specifications of a sewerage scheme with tidal outlet at an estimated cost of £2750. At a meeting of Dolgelly rural council on Nov. 6th the sanitary inspector reported structural alterations at a number of farmhouses, and it was agreed to call the attention of owners to the fact that owing to lack of accommodation the practice was exceptionally common in one parish of storing wool, corn, &c., in dwelling houses. The medical officer reported having examined two houses where cases of tuberculosis had occurred. The houses were scrupulously clean and structurally satisfactory, but all the windows were closed. That was to him a sad and distressing state of things and it was evident that the public were not yet convinced of the efficacy of fresh air, notwithstanding the council's efforts to bring that knowledge home to the minds of the people. Cases of scarlet fever continuing to occur he again drew attention to the necessity of providing proper isolation. It was useless closing elementary schools if those who were infected attended chapel and other meetings. The chairman feared that the public were not yet sufficiently advanced to agree with the views which the medical officer had repeatedly expressed with regard to the isolation hospital and the council took no further action.

Bebiebs and Notices of Books.

Arthritis Deformans: Comprising Rheumatoid Arthritis, Osteo-arthritis, and Spondylitis Deformans. By R. LLEWELLYN JONES, M.B. Lond. With 38 full-page plates. Bristol: John Wright and Sons, Limited. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1909. Pp. 365.

THE subject of chronic diseases of joints is one concerning which our knowledge is far from complete, and opinion in regard to these conditions is now in a state of flux. Modern scientific methods of research have established the fact that under the name of arthritis deformans and its numerous synonyms a number of joint conditions are included, which, though owning certain superficial resemblances, differ in regard to their morbid anatomy, distribution, and causation. The numerous classifications of these conditions are an index of the confusion existing in regard to them, a confusion still further increased by the varying nomenclature adopted by different authors. In the useful book before us Dr. Llewellyn Jones at the outset states that he employs the term arthritis deformans in a generic sense, and he proceeds in an introductory chapter to give an interesting historical account of these conditions, with numerous references down to the year 1902. The second chapter deals with the classification of arthritis deformans and includes references down to last year. Various classifications are discussed, including those of Charcot, Osler, Pribram, and Goldthwait; the last-named observer has suggested a grouping on pathological lines into (1) infectious arthritis; (2) atrophic arthritis; and (3) hypertrophic arthritis. Dr. Jones is not prepared to go so far as this. and adopts a division into two main groups: (1) rheumatoid arthritis; and (2) osteo-arthritis, including under the former not only the atrophic arthritis of Goldthwait, but also the more acute forms of rheumatoid arthritis showing glandular and occasional splenic enlargement, including "Still's disease," all of which would be referred by Goldthwait to the group of infectious arthritis. In this group "the morbid changes occur primarily in the softer structures. the peri-articular and synovial tissues undergoing thickening with hypertrophy of the synovial fringes, while ultimately a process of atrophy involving all the constituent elements of the joints takes place, including the bony and cartilaginous as well as the softer tissues." In osteoarthritis, as defined by Dr. Jones, the primary changes take place in the cartilaginous and bony structures, which undergo enlargement with the formation of osteophytic outgrowths. This osteo-arthritic group is subdivided into generalised and localised forms. It is probable that any classification will have to be modified as our knowledge advances, but meanwhile that of Dr. Jones possesses the merits of simplicity and comprehensiveness.

Rheumatoid arthritis is then discussed at some length, special chapters being devoted to its etiology, bacteriology, morbid anatomy, pathogeny, premonitory symptoms. general clinical features, diagnosis and prognosis, and treatment. In connexion with etiology, the rôle of antecedent gastro-intestinal disorders is specially discussed. and Dr. Jones confesses to a leaning towards a toxemic theory of the origin of the condition, while admitting that the etiology of many cases is still obscure. The chapter on the bacteriology of the disease gives a review of the claims of various authors, but the conclusion arrived at is that the infective theory of the origin of rheumatoid arthritis, though strongly suggested by some of the clinical features, is still not conclusively established. In regard to the morbid anstomy the changes are regarded as occurring primarily in the synovial and peri-articular tissues, the changes in the

cartilage and bone being secondary, while eventually atrophic changes occur, in which even the shafts of the bones may participate. As a result of the denudation of the bony surfaces of the joint, cancellous bone comes into contact with cancellous bone, and true bony ankylosis occurs, not infrequently with a tendency to obliteration of the joint cavity. Such bony ankylosis occurs rarely if ever in osteo-arthritis. In connexion with pathogenesis Dr. Jones discusses the neural and infective theories which have been put forward to account for the genesis of the disease, but thinks that it is best explained as a cerebro-spinal toxæmia or as a trophoneurosis of infective or toxic origin, which is in effect a combination of both theories. He claims that rheumatoid arthritis possesses affinities with tetany and with Raynaud's disease, and regards all three diseases as the expression of a cerebro-spinal toxemia. The chapter on premonitory symptoms is one worthy of special note, owing to the importance of the recognition of the disease in its earliest stages. These symptoms are discussed under the heads of vaso-motor, motor, sensory, and reflex. The subject of treatment is dealt with at considerable length. importance of the treatment of oral sepsis and pyorrhœa alveolaris is rightly insisted upon. In regard to drug treatment Dr. Jones writes favourably of the use of quinine, which he prefers to guaiacol carbonate. He has also found thyroid extract of value in the treatment of cases associated with vaso-motor phenomena. Balneo-therapeutic measures, electrical, and other forms of treatment are also described in detail.

The third section of the book deals with osteo-arthritis—which is considered after the same general plan as the rheumatoid arthritis. In this condition the primary changes are regarded as occurring in the bony and cartilaginous structures, while the synovial tissues are only affected secondarily. Various localised forms of this condition are described in detail, including Heberden's nodosities, "malum coxe senilis," and osteo-arthritis of the knces. The diagnosis from rheumatoid arthritis, chronic gout, and the nervous arthropathies is discussed. In regard to treatment, Dr. Jones believes that he has found guaiacum and sulphur the most useful combination as a routine method of treatment, but states that arsenic has done good in some cases.

The fourth section is devoted to spondylitis deformans. An interesting historical account is given of this condition. Two types are differentiated, the Strümpell-Marie and the von Bechterew. This condition, like the peripheral type of arthritis deformans, appears to be capable of division into rheumatoid and osteo-arthritic forms. The diagnosis and treatment are briefly discussed. The concluding section deals with the subject of arthritis deformans in children, under which heading the condition known as Still's disease is described.

Dr. Jones has produced a useful monograph, which forms a valuable addition to the literature of this complex condition.

Surgical Anasthesia. By H. BELLAMY GARDNER, M.R.C.S. Eng., L.R.O.P. Lond. London: Baillière, Tindall, and Cox. 1909. With 35 illustrations and 12 plates. Pp. 240. Price 5s.

This book has one advantage not always to be found in works on special subjects: it is easy to read. That this is the case results no doubt from great care bestowed upon the writing of it by a man who is thoroughly versed in the subject of which he treats. Another factor which lightens the reading of his book is that Mr. Gardner has not overloaded it with the opinions or practice of other authorities, and in a small work of this nature we take it for a gain that the teaching should be individual, though faults may arise naturally from this attitude. We think, for instance,

that Mr. Gardner has not, when treating of chloroform, laid sufficient emphasis upon the importance of low vapour percentage, and he has not even mentioned the best forms of apparatus devised for securing this end. He describes, indeed, the Vernon-Harcourt inhaler, but he ignores entirely those instruments which work upon the "plenum" system and which are, in the opinion of many, preferable for several reasons to the aforementioned inhaler.

Again, in his otherwise excellent little chapter on adenoids. the author should, we think, lay more stress upon the fact that safety lies primarily in a light degree of anæsthesia; that this is so at any rate when a not very experienced administrator has charge of the anæsthetic there can, we think, be no doubt, and it is particularly for the comparatively inexperienced that this book is designed. The fact is that Mr. Gardner is so impressed with the immense importance of avoiding all forms of obstruction to the breathing that he is comparatively indifferent to the question of the strength of vapour. All his teaching upon the first of these two points is excellent. It is clearly explained and most emphatically stated. The second factor, however, is surely of at least as great moment. Fatal consequences can be brought about though the airway be perfectly free, provided that too much chloroform is given, while if the airway be obstructed a catastrophe is less probable, provided that the vapour inhaled is really a very weak one. We do not wish to belittle in any way the baneful influence of even those slighter forms of asphyxial complications which Mr. Gardner describes so well, but we wish he had treated more fully the question of overdosage and the extreme ease and rapidity with which it may be brought about by those who have not from long usage realised the potency of chloroform vapour.

Mr. Gardner has a predilection for the mixture of chloroform and ether in the proportions of 1 to 2. That some such mixture is the most desirable as the routine ansesthetic in the hands of those who are not specialists seems to be his opinion, and is one with which most authorities will, we believe, agree. The book contains an accurate description of the nasal method of administering nitrous oxide with or without oxygen, a method for which Mr. Gardner evidently has a stronger liking than is, we believe, common amongst anæsthetists. On this, however and one or two other matters of opinion we do not wish to enlarge, for we cordially welcome Mr. Gardner's book as a capital exposition of the principles and practice of ansesthesia as these appear to one very well qualified to describe them from his own experience.

The Public Health Agitation 1833-1848. By B. L. HUTCHINS. London: A. C. Fifield. 1909. Pp. 150. Price 2s. 6d.

It seems a far cry from the present day to the time of the passing of the first Public Health Act in 1848, and a still farther cry to the memorable agitations which, continuing through the third and fourth decades of last century, led to the placing of that measure on the Statute Book. Among present-day sanitarians there can survive but few contemporaries of those earlier pioneers of public health, Edwin Chadwick, Southwood Smith, and their followers. And among those still fighting the battle of public health there are not many who were familiar with the immediate successors of those pioneers-e g., Sir John Simon and Dr. Edward Rumsey. Of Dr. Southwood Smith no biography has been written, with the exception of a brief memoir by his granddaughter, Mrs. Lewes, and the only existing record of the life work of Sir Edwin Chadwick is contained in a treatise on the "Health of Nations," by his friend and admirer, Sir Benjamin Ward Richardson.

book which, although not pretending to be a history of public health, "aims," in the author's words, "at a presentment of some of the more striking figures in the initial movement towards sanitary reform that began with the Poor-law report and ended with the General Board of Health in 1854." The present volume, which embodies a course of lectures recently delivered at the London School of Economics, is one of a series evidently designed for the support of certain doctrines of the so-called "Collectivist" school, an aspect in which a notice of the work would hardly be appropriate to our columns. Incidentally, however, Miss Hutchins gives an account of the life and public health work of Edwin Chadwick and of Southwood Smith, the like of which has not previously been presented in one volume, and from this point of view a brief notice of the work will probably be interesting to our readers. Its chief materials have been derived from the reports on sanitary inquiries issued by the Poor-law Commissioners in 1838-9. Frequent reference is, of course made to Sir Benjamin Richardson's collection of the writing of Edwin Chadwick, and to Sir John Simon's work on English sanitary institutions, as well as to Dr. Redlich's treatise on English Local Government.

The book opens with an interesting account of Sir Edwin Chadwick's life and work from his birth in 1800 to his death 90 years later. The chief events recorded in his life are: the part he took as a member of the Factory Commission in 1833, and particularly his advocacy of the appointment of paid inspectors of factories under central control; his work in 1834 as a Poor-law Commissioner; his efforts towards the establishment of an office for the registration of births and deaths; and, lastly, the prominent part he took in the agitation for sanitary reform and in the formation and work of the General Board of Health in 1848. Of the life and labours of Dr. Southwood Smith, who was Chadwick's senior by 12 years, an interesting account is given. His professional life in London dates from 1820, in which year he settled in the East End, shortly after which he was appointed physician to the London Fever Hospital, to the Eastern Dispensary, and to the Jews' Hospital in Whitechapel. From this point may be said to date his career as a sanitary reformer. His personal experience of work among the sick poor gave him a knowledge of their lives and habits which stood him in good stead in his subsequent career. In 1833 Dr. Smith was appointed a commissioner to inquire into the employment of children in factories, this being his first appearance as an investigator under Government. In 1837 he was appointed by the Poorlaw Commission to report on a serious epidemic of fever in East London. After personal visitation of the houses and their fever-stricken inhabitants in Bethnal Green and Whitechapel, he pointed out how intimate was the connexion between the fever prevalence and the poverty and fearfully insanitary conditions in which the people had to live. Out of the total recipients of Poor-law relief in Bethnal Green just one-third part were at that time the subjects of fever; in Whitechapel, one-half; whilst in the parish of St. Georgethe-Martyr the number of fever-stricken paupers was 1276 out of a total of 1467. This was the kind of first-hand observation which enabled this country to be the pioneers in the world of sanitary science and preventive medicine, and Miss Hutchins has done good service by presenting the results of her reading in convenient booklet form at a low price. Unwittingly, she has, we think, been led to attribute to Chadwick alone some of the higher qualities of statesmanship which rightly belong to Southwood Smith in at least an equal degree. The former was the energetic, fearless agitator constantly before the public, Miss B. L. Hutchins has now written an interesting little whilst the latter, working unostentationally in the slums

and in the fever wards of London, doubtless provided much of the material upon which the former relied for his successful encounters with ignorance and prejudice. The book deserves to be commended to the study of all those who are interested in the further progress of sanitary

LIBRARY TABLE.

Self-Help for Nervous Women: Familiar Talks on Economy in Nervous Expenditure. By JOHN K. MITCHELL, M.D. London: William Heinemann. 1909. Pp. 202. Price 2s. 6d.— The author of this book has had ample experience in Philadelphia of studying nervous diseases, and is in a position to speak with authority as a physician to physicians. This little book is, however, addressed to patients and relatives of patients; it is free from the technicalities of medicine and written in a style familiar and easy but not devoid of dignity and signs of careful composition. The whole book is thoroughly good sense. Dr. Mitchell is quite free from fads in his survey of this fad-ridden subject, and he has a very good sense of proportion in his estimate of the causative factors of neurasthenia and other questions concerned in its study. Thus he insists that "nervousness' is a symptom, rather than a pathological entity, though The lays stress later on the important point that all cases of neurasthenia are the result of starvation of nerve cells, and he is quite alive to the frequency of intestinal intoxication as a causation. In the author's opinion it is clear that trauma as the determining origin of mild neurasthenia has been unfortunately overexaggerated by the medical profession; where slight accidents appear to start neurasthenia there must have been gradual preparation of the nervous system for a long antecedent period. We have translated ideas found in Dr. Mitchell's book into the language of the neurologist, but he expresses them very simply and easily in ordinary colloquial phrases, and shows thereby that he has acquired great practice in advising laymen on such matters. There are some excellent remarks on religion and suggestion, and in the concluding chapter a very sound and temperate criticism on the Emmanuel movement, a method which Dr. Mitchell -considers undesirable or impracticable for most ministers to attempt, however successful in the hands of its originators. The broad common-sense of the remarks on the food of neurasthenics commends itself to us especially. There are also admirable suggestions on the training of mild neurasthenics in the arrangement and plotting of their time and occupations, things which we all know to be essential in giving practical advice. This book may be placed with advantage to physician and patient in the hands of the mothers, relatives, or advisers of the latter.

Astronomical Curiosities, Facts, and Fallacies. ELLARD GORE. London: Chatto and Windus. 1909. Pp. 370. Price 6s. net.—Astronomy is a subject about which there is perhaps more general ignorance than about anything else, and considering that simple astronomical phenomena are to be seen on most days and nights of the year, even in such a cloudy and sunless year as the present, this is by no means a creditable state of things. Mr. Gore's interesting little book is perhaps somewhat advanced for the amateur astronomer, even for him who has arrived at the fact that the moon as a crescent, popularly called "new," sets only a little after the sun, and that the full moon rises as the sun sets. But anyone who has even a rudimentary knowledge of the heavenly bodies will be inspired to learn something more than he knows by reading Mr. Gore's pages. Medicine nowadays has but little to do with the motions, positions, or composition of the stars and planets, except in so far that certain of the sun's rays may opening into the dorsal or hyperbranchid coelom described

have some influence upon metabolism, or may exercise an influence upon pathogenic bacilli. But it is good for all of us to have some knowledge of the stars and of the phenomena by which we are surrounded, and Mr. Gore has brought together a number of interesting facts and fallacies about astronomical matters. A small amount of astronomical knowledge is of value in general reading and necessary to the comprehension of many passages in the earlier medical writers and the classics.

Why Worry? By GEORGE LINCOLN WALTON, M.D., Consulting Neurologist to the Massachusetts General Hos. pital. London: William Heinemann. 1909. Pp. 275. Price 2s. 6d.—This is one of the "Simple Life Series," which appears to derive its family name because the volumes are issued in order to be purchased by the victims of conditions which are the reverse of a simple life. Slight and trite describes the volume. The opening chapters drag in hasty sketches of Epicurus and Marcus Aurelius, with a few apophthegmata culled from them. The remainder is a series of rambling disquisitions not devoid of humour on neurasthenia, hypochondria, insomnia, and kindred subjects; but we very gravely doubt if "worriers," neurasthenics, and hypochondriacs would derive any benefit from the book. It is a pleasure to find the author insisting on the proper pronunciation of neurasthenia. Exception may be taken to the use of the word "fad," as employed by Dr. Walton. The word is interesting because philologists can assign no derivation, but it is of entirely modern use. Murray's Dictionary defines it as "a crotchety rule of action"-"a peculiar notion as to the right way of doing something," which seems an admirable description of the meaning. The author, however, employs it as a synonym for "hobby," and his chapter on the cultivation of the hobby is excellent, quite the best in the book.

The Climate of Strathpeffer. By H. W. KAYE, M.D. Oxon. London: Sonnenschein and Co. 1909. Pp. 64. Price 2s. 6d.--A third of this volume consists of a dry and somewhat weakly written abstract of the principles of elementary meteorology; the remaining pages, which are of real value, give a careful synopsis of the peculiarities of the climate of Strathpeffer. Dr. Kaye presents a number of statistical tables in proof of the claims he makes in favour of a climate which is of small area, and the resultant of unusual geographical features. The climate of Strathpeffer is very peculiar and can only be appreciated by those who have experienced it. To visitors interested in meteorology this modest but accurate little brochure will be of assistance.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by Sir RAY LANKESTER, K.C.B., F.R.S., with the cooperation of ADAM SEDGWICK, F.R.S., SYDNEY J. HICKSON, F.R.S., and E. A. MINCHIN, M.A. London: J. and A. Churchill. New Series, No. 214 (Vol. LIV., Part II.). October, 1909. Price 10s. net. - This part contains four memoirs, of which the first is on Dendrosoma radians, Ehrenberg, by Sydney J. Hickson and J. T. Wadsworth, with a plate. Dendrosoma is an acinetarian allied to trichophrya, lernæophrya, and astrophrya. It was first described by Ehrenberg and subsequently by Claparède and Lachmann. It has been found in Europe and in the United States. It appears to feed on euplotes and on paramecium. Reproduction is effected by the formation of internal buds or gemmules, which are plano-convex in form and have several contractile vacuoles and a broad band of cilia. Their development is described. 2. On the Structure of the Excretory Organs of Amphioxus, by Edwin S. Goodrich, F.R.S., with five plates and one text figure. Mr. Goodrich is firmly convinced that the internal funnels of the nephridia

by Boveri and others do not exist. His observations on the larval nephridia he summarises as follows. To every gill slit corresponds a nephridium consisting of a sac closed internally but opening to the exterior apparently at the point where the ectoderm joins the entoderm in the shallow branchial chamber. From the internal blind end of the nephricial sac spring numerous solenocytes, some of which reach and spread over the aorta at every segment in a fanlike arrangement. This structure is only developed from about the eighth segment backwards to the last nephridium. 3. Intracellular and General Digestive Processes in Planaria, by G. Arnold, Cytological Laboratory, Liverpool, with a plate. The author shows that digestion in Planaria is both inter- and intra-cellular. The intercellular digestion is limited to fat. The fat is broken down in the lumen of the intestine by the secretion of the goblet cells into fatty acids which are then absorbed by the columnar cells, and synthesised again into neutral fat. Most of the fat is digested in the cytoplasm of the columnar cells, but some of it is extruded into the parenchyma at their base and appears in the yelk cells and in the wandering cells. The digestion in the vacuoles takes place in an acid medium, as evidenced by the change in the staining reaction of ingested leucocytes. 4. Professor Hubrecht's Paper on the Early Ontogenetic Phenomena in Mammals: an Appreciation and a Criticism, by Richard Assheton, M.A., Trinity College, Cambridge.

Rew Inbentions.

STERILISED DRESSINGS.

THE demands of scientific surgery and the requirements of modern medicine have influenced pharmacy to a great degree, and the advance of the present-day pharmaceutical chemist on the methods of a few years ago shows that this progress has been very closely followed up by the pharmacists. The perfection to which the sterilisation of surgical dressings has come to be brought is a case in point. sterilised dressings for surgical work must be prepared nowadays with an amount of care and exactitude that necessitates the use of elaborate machinery; no detail in the work is trivial, none can in any way be slurred over, for the consequences that may follow defective sterilisation are of the utmost seriousness. Messrs. John Bell and Croyden have submitted to us for examination metal drums containing various suitable sterilised dressings ready for immediate delivery day or night. We have inspected and tested the contents of these drums and find that the sterilisation has been thoroughly performed. We visited the premises of Messrs. Bell and Croyden at 50, Wigmorestreet, London, W., and inspected the sterilising autoclave installed there in two specially designed chambers. The apparatus is one of Manlove and Alliott's latest types of high pressure machines, and has been erected so that the inlet is in one room and the outlet in another. The drums are filled and placed in the autoclave from the inlet side, the air is then exhausted to 20 inches pressure, steam at a temperature of at least 260° F. and 20 pounds pressure is next forced through the dressings for 20 minutes, and lastly a vacuum of 20 inches is produced for 20 minutes, abstracting the steam and leaving the dressings perfectly dry. The outlet room contains air obtained from above by means of a powerful electric enclosed fan, having a front of fine wire gauze covered with wetted lint, the air being thus filtered. The outlet room is filled with steam so that all particles of dust are thrown down before the operator opens the autoclave. After putting on sterilised clothing and gloves, but before removing the drums, he places metal discs in position on them as they are in the autoclave, and at once solders down the discs with an electric soldering iron, the object being to secure the hermetical sealing of the tins aseptically. Both rooms have glasslined walls with rounded corners, and are washed daily with carbolic (1-20). An automatic chart registers the temperature, steam pressure, number of inches of vacuum pressure, and length of time the articles have been subjected to the process. When required for use by

the surgeon the drums are opened by tearing off the soft metal band, when the lid can be removed easily. The drums cost so little that there is practically no increase in the price of the dressings. saturated steam under pressure for sterilising possesses great advantage because it not only drives out air quickly and penetrates to the interior of dressings rapidly and certainly, but because it also possesses such a high temperature. By the means described above Messrs. Bell and Croyden are able to guarantee that the dressings in the drums are sterilised at a temperature of at least 260° F. and 20 inchesvacuum pressure. A telephone message day or night will ensure a supply of these sterilised dressings being sent by motor, by cab, by cycle, or by rail. A qualified pharmacistis on duty at 50, Wigmore street at night and during Sundays. with a porter in attendance. In this way dressings and, if necessary, operating tables with all antiseptic accessories can be supplied at once on emergency to any address, and we can vouch personally for the fact that in spite of the necessary hurry the arrangements work perfectly smoothly.

COMBINED STETHOSCOPE AND PERCUSSOR.

THE illustration represents an instrument made for me by Messrs. C. J. Hewlett and Son, Limited, of Charlotte-street,

London, E.C., with the view of combining auscultation and percussion. By the usual appliances used for the latter purpose a considerable amount of sound is lost which can and is by this instrument carried directly to the ear, either from the patient's body or indirectly by attaching the side tubes of flexible metallic tubing (removeable) to projections on the pleximeter; on reversing the thimble it will form the bell-end of a binaural stethoscope. There is an obvious advantage of combining two instruments in one which with a pleximeter will fit in a small flat box.

ALEXANDER DUKE, F.R.C.P. Irel.

CHICHESTER INFIRMARY.—Notwithstanding the economies effected in the expenditure, the governors of the Chichester Infirmary, which serves West Sussex and part of Hampshire, are faced with a deficit of nearly £1500, a sum which would have been much greater but for a munificent gift from a donor, who has before contributed so largely to the funds of the institution. Its work during the year just ended has been in excess of any previous year, the inpatients numbering 766, or 79 more than in 1903, while 1990 out-patients have been treated, in addition to 207 in their own homes. The governors at the annual meeting on Nov. 11th appointed a subcommittee to consider how to improve the finances. It is stated that the King may give his patronage by permitting the institution to use the name of "The Royal West Sussex and East Hants Hospital and Chichester Infirmary" when the debt has been liquidated.

MEDICAL MISSIONARY INSTITUTION GERMANY.—A medical missionary institution has been established in Tübingen under the direction of Dr. Fiebig, who was for 10 years in the Datch East Indian Service. The second director is Dr. Olpp, who was for a long period a medical missionary in China. The institute will combine the functions which in this country are carried on by the Edinburgh Medical Missionary Institution, where the students qualify as medical men, and the Livingstone Medical College in London, where a partial medical education is given to missionaries. The Tübingen Institution also arranges for the training of lady doctors and for that of midwives and nurses who are going abroad as missionaries. There will also be a hospital for the treatment of missionaries and of other Europeans from tropical countries. The teaching staff includes several of the University docenten. Thisinstitution is mainly due to the munificence of Herr Paul Lechler, a large manufacturer, who is president of the Stuttgart Medical Missionary Society, and the University of Tübingen has just created him an honorary Doctor of Medicine.

THE LANCET.

LUNDON: SATURDAY, NOVEMBER 20. 1909.

The Rôle of Radium.

THE innate optimism of the human race naturally renders us prone to expect great things from new inventions and dis-Sometimes we overestimate the benefits to be derived from the innovation. Sometimes, though less frequently, we underestimate, or at least appreciate erroneously, the benefits, and this has been the case with radium, for we are coming to the belief that its potentialities are very great indeed. We need not take into account the unconsidered prophecies of those who knew nothing of the nature of disease, and especially of the conditions in which radium was being employed, for such observers as these are always liable to expect too much; but the learned in matters therapeutic have perhaps erred on the opposite side. The quantities of radium available for research in treatment are nearly always so small that it is somewhat unsafe to base any definite conclusions on the results obtained by the use of such minute quantities of the material. Some recent investigators, however, have had the good fortune to have placed at their disposal quantities of radium which may by comparison be termed enormous, though if we contrast them with most other ponderable substances they seem indeed minute.

In many of the crude drugs of our Pharmacopæia are included various powerful substances possessing actions very different from one another. In opium, for instance, there exist some ten or twelve alkaloids at least, and when these are obtained in conditions of purity, and are examined physiclogically, we find that while some of these possess the sedative properties of the drug itself, others are definitely convulsants, and others again possess different properties still; and the action of the drug as a whole is compounded of the united action of the many constituents in various proportions according to the source whence the drug is derived. So also is it with radium. We possess in a small degree the power of physical analysis of the radium rays, and we find that what was at one time looked upon as very simple is now seen to be a mingling of rays of many different kinds and powers. These have been named simply and uncommittingly after letters of the Greek alphabet. We have alpha rays, beta rays, and gamma rays, differing one from the other in various properties. Their effects on the tissues are strangely different. But it is in the power of passing through metallic screens where the most obvious differences exist, and we employ this variation in penetration not merely for purposes of classification but also for filtration, so as to separate the rays of one kind from the rays of another. The alpha rays, which form a very large percentage of the total radium rays, are of low penetrative

power; a very thin plate of silver suffices to occlude them completely. Their effect on the tissues is chiefly manifested by the skin, which inflames readily and sometimes to a great degree, but the underlying tissues suffer little or not at all, so far as we know at present, from the alpha rays. The beta rays possess greater power of penetration and form but a small part of the total rays; they affect the superficial structures of the body to a very slight degree, but they cause changes to take place in the deeper tissues. The somewhat artificial method of classification divides these rays according to the thickness of metal which they are able to penetrate, but a closer examination of the beta rays has convinced careful observers that under this one heading are included rays possessing different powers-BAUDOIN for example, recognising three different classes; and this may be true of the gamma rays, which can pass through greater thicknesses of metal than any of the beta rays. Research hitherto has not rendered it necessary to go farther down the alphabet to provide names for radium rays, but, in fact, the radium gamma rays are analogous to ether rays of light and heat, effects being produced of different natures as we pass along the scale; just as at one part of the spectrum are invisible heat rays, then visible light rays, and lastly invisible rays again possessed of actinic power.

We know as yet but little of the therapeutic properties of radium, and the knowledge which we do possess is almost limited to the less penetrating rays. Numerous papers have appeared within the last year or two and the knowledge we possess is fixed on a firm basis. We know that it is possible by means of radium to influence favourably many superficial conditions, such as nævi, especially capillary nævi and birth-marks. Lupus vulgaris is also amenable to its influence and the scars produced are soft and supple and in every way as good as can be obtained by any other means. Some cases of lupus erythematosus also have improved greatly under radium treatment. Keloid, too, which ill repays any surgical interference, has proved to be beneficially affected by radium rays. Many other superficial conditions could be mentioned in which radium has shown itself capable of so modifying the abnormal tissues present as to lead to their disappearance and their replacement by healthy scar-tissue. Rodent ulcer also is undoubtedly curable by radium, and the skin when the disease has been removed may show barely a trace of it. For deeper affections more hesitation must be employed in describing the results, for all observers are not agreed as to the capabilities of radium. This much is certain; in order to obtain the deeper effects it is necessary to filter off by means of metallic screens those numerous rays which have little power of penetration, but which are capable of giving rise to troublesome and unnecessary dermatitis. The more penetrating rays which pass through the filter are small in quantity, and hence it follows that much larger amounts of radium are necessary if it be desired to attack structures deeply situated. The scarcity and the consequent expense of radium limit greatly its utility and also the extension of our knowledge of the subject. The lecture of Dr. L. WICKHAM last spring in London and again at the British Medical Association meeting at Belfast aroused

great interest in the capabilities of radium in dealing with the deeper forms of malignant disease, and it may well be that increased experience with radium will increase the range of its applicability, but at present too much must not be expected. To THE LANCET of Nov. 13th Mr. BUTLIN has contributed a most valuable criticism on the results obtained by radium in cases which had been under his care. In every case the application was made by someone experienced in its use, so that Mr. BUTLIN'S cases and his conclusions are well worth study. In one case a small epitheliomatous ulcer healed under the treatment, but in several other cases any beneficial effect was merely temporary, and in no case did it appear that the enlarged lymphatic glands were favourably affected. We concur fully in his view that in cases of epithelioma of any but the smallest extent we are not yet justified in advising patients whose disease is amenable to operation to try the effect of radium, unless there are circumstances in the individual case which render an operation inexpedient. The attitude to be observed towards radium as a therapeutic agent is, on the whole, expectant. Many conditions, for the most part superficial, are definitely controllable by its use, as they are by other remedial procedures. As to more deeply situated lesions, no very certain words can yet be spoken, but we may look forward with some degree of hope that further experience with large quantities of radium and further knowledge of the value of screening off the less penetrating rays may enable us to deal with deeply seated malignant growths.

The Physiology of Gastric Secretion.

In the history of our knowledge of the processes of digestion within the stomach the researches of BEAUMONT and of PAWLOW stand out with especial prominence. Professor G. N. STEWART has pointed out, it is difficult to speak without enthusiasm of the work of BEAUMONT, if we consider the difficulties under which it was carried on. An army surgeon stationed in a lonely post in the wilderness that was then called the territory of Michigan, a thousand miles from a university, and four thousand from anything like a physiological laboratory, he was accidentally called upon to treat a gun-shot wound of the stomach in a Canadian voyageur, ALEXIS ST. MARTIN. His observations, published in 1825 and 1833, laid the foundation of all the subsequent work upon artificial gastric fistula, a method which was so ingeniously employed by PAWLOW in his now classical researches dating from 1889 onwards. The influence of the experiments of PAWLOW and his pupils upon subsequent work in regard to the study of gastric digestion in both man and animals it would be difficult to over-estimate.

In man, unfortunately, the operation of gastrostomy is most frequently performed upon cases of malignant disease, which are therefore unsuitable for purposes of physiological observations. A few, however, are on record where it has been performed on healthy stomachs owing to cicatricial stenosis of the œsophagus. Such a case has recently been studied by Dr. R. S. LAVENSON of Philadelphia, who records his observations in a highly instructive paper in the September number of the Archives of Internal

Medioine. He also gives an interesting résumé of previous work upon the subject. The patient was a girl, 14 years of age, upon whom 11 years previously the operation of gastrostomy had been performed for a complete occlusion of the esophagus due to scarring from drinking lye. The patient fed herself by means of a small tube, one end being inserted into the gastric fistula, the other end being tied with a string about the neck. During meals she partook of liquid and semi-solid foods, which she masticated and swallowed in the ordinary way until about three ounces had been taken. She then put her mouth to the tube and by a slight voluntary effort of regurgitation brought the food from the pharynx and cesophagus into the mouth and thence she forced it down the tube into the stomach. The conditions were thus analogous to the well-known experiment of PAWLOW, and Dr. LAVENSON hoped to have been able to demonstrate the influence of psychic stimuli in bringing about gastric secretion by appealing to the various senses with food and collecting the gastric juice by means of a catheter passed through the fistula. In this he failed owing to the fact that though the patient desired to assist in every way in the experiment it was as such distasteful to her, a mental attitude being induced which was sufficient to inhibit the effect of the psychic stimuli investigated. It is of interest to note in this connexion the influence of emotion on secretion as seen in animals. BICKEL and SASAKI 1 performed false feeding observations upon a dog with cesophageal and gastric fistulæ, and found in an experiment that 66.7 cubic centimetres of gastric juice were collected in the first 20 minutes afterwards. This particular dog was found to become violently enraged at the sight of a cat. After being excited by this means for five minutes and then allowed to calm down, a false feeding was carried out in the same manner as in the previous experiment, but only 9 cubic centimetres of gastric juice was secreted in the same period of time. The influence of psychic factors has been established in the human subject by CADE and LATARJET, BOGEN, KAZNELSON, and UMBER. In KAZNELSON'S patient a gastrostomy had been performed for cicatricial stenosis of the esophagus and some years later an esophagostomy was performed, a tube being passed down through the pharynx and out of the cesophageal fistula to communicate with another tube entering the gastric fistula. KAZNELSON 2 was able to confirm on this patient practically all PAWLOW'S observations on false feeding. The simple act of chewing did not call forth a flow of gastric juice, but the mastication of foods pleasing to the patient produced an abundant flow after a latent period of about five minutes. It was found, also, as PAWLOW found in animals, that the acidity of the gastric juice was practically constant, but that the amount of secretion was subject to marked variations.

Being unable to investigate the effects of psychic stimuli on his patient Dr. LAVENSON proceeded to make observations on the effects of chemical stimulation. The results obtained showed that the human stomach reacts in the same way as that of the dog. Water was found to be a definite though not a powerful chemical stimulus to gastric secretion.

¹ Bickel and Sasaki: Deutsche Medicinische Wochenschrift, 1906 vol. xxx., p. 1829.

Pflüger's Archiv für die gesammte Physiologie, 1907, vol. cxviii., p. 327.

This result is one of importance, since the effect of soluble substances must be compared with that of the water used in dissolving them-e.g., tea, certain commercial solutions of pepsin, and egg albumin dissolved in water did not cause the secretion of any more juice than an equal quantity of water. Dilute hydrochloric acid introduced into the stomach did not cause any secretion of gastric juice: on the other hand, beef extracts proved to be powerful stimulants to secretion. Interesting results were obtained with the bitter stomachics such as tincture of nux vomica and tincture of gentian. They proved to be incapable themselves of inducing a secretion of gastric juice, but if given before a substance such as beef extract they increased the secretion produced by it, and thus appeared to act as sensitisers of the gastric secretion. Another interesting result obtained was that a bitter stomachic taken into the mouth caused a greater effect than if it were introduced directly into the stomach. These results in regard to the action of bitters are in accord with those of Borrisow, HOPPE, and KAZNELSON. A nutrient enema administered when the stomach was empty caused a flow of 12 cubic centimetres of rather viscid gastric secretion, with free hydrochloric acid in it. From the effects obtained by introducing acid and alkaline solutions into the stomach Dr. LAVENSON believes that the predominating influence in the control of the periodic opening of the pylorus is exerted by the chemical reaction on the duodenal side of the pylorus. The experiments of CANNON³ have shown that an acid reaction on the gastric side of the pylorus and an alkaline reaction on the duodenal side tend to open the pylorus, while an acid reaction on the duodenal side and an alkaline on the gastric side tend to keep it closed. Dr. LAVENSON found that the chemical reaction prevailing on the gastric side of the pylorus is of subordinate importance to that on the duodenal side. The interest of these observations is that they indicate that the duodenum is capable of preventing too great a discharge of the acid contents of the stomach at once, and also that they explain the slow discharge of gastric contents of high acidity and the more rapid passing on of those of low acidity. Dr. LAVENSON's paper is a highly instructive and suggestive résumé of recent work upon gastric secretion and motility, and is of special value since it confirms the results obtained by other workers.

The International Opium Commission.

No person, lay or medical, will in the present day deny the gravity of the opium question in the Far East, nor will anyone acquainted with the subject make light of the many difficulties which surround the question as to how it can best be dealt with. The proceedings of the International Commission which met at Shanghai early in the present year are made known in the report which has recently been published. The Commission comprised 32 members, of whom only four were medical men. As might have been expected, this shortage of medical representation was soon felt when the opium habit and its evil consequences to

mental and bodily health came to be considered. A proposal was made by the Chinese delegation that a committee consisting of five delegates should be appointed to consider and report on the medical aspects of the opium question, including the best methods of curing the opium habit without recourse to the drug or any of its derivatives. This resolution was opposed by the British delegation on the ground that the Commission was not appointed on a scientific basis, and suggestion was made that this matter should be brought by the various delegates to the attention of their respective Governments, which would alone be able to appoint competent experts to make the necessary investigations. It was stated in the course of the discussion that there were only three of the medical representatives on the Commission capable of taking part in such an inquiry. During the discussion Dr. HAMILTON WRIGHT, one of the American delegates, pointed out that when Her late Britannic Majesty's Royal Commission on Opium was appointed the British Government thought it sufficient to appoint only one medical expert; that the report of that expert had coloured to a great extent the final judgment of the Royal Commission, and had not proved satisfactory to the majority of medical men who had taken trouble to examine it in detail. Dr. WRIGHT argued that if one medical expert was regarded as sufficient to investigate the medical aspects of the opium question in a Royal Commission, three experts would suffice for the International Commission's purposes. We entirely agree with Dr. HAMILTON WRIGHT'S view that the medical examination of the opium question should be placed upon a modern footing. While admitting the very important fiscal and diplomatic questions which had to be discussed by the Commission at Shanghai, we hold that the opium vice and its prevention and cure are matters needing careful investigation by medical experts. We regret, therefore, that at least one competent medical practitioner was not included among the British delegates sent to the recent International Commission. The other nations chiefly concerned in the opium question—namely, China, Japan, and America—all sent medical representatives to Shanghai. The German delegation, though not medically represented, was in complete sympathy with the professional view, and expressed the opinion through its chief delegate during the discussion that "the medical side of the opium question was the issue of the anti-opium campaign." With this view we are in entire concurrence, and we earnestly trust, when the proposed International Conference on the Opium Trade is held at the Hague, negotiations as to which are now, we understand, proceeding, that the Government of Great Britain will give due attention to the medical aspects of the question, and will include among her representatives one or more competent medical experts who will, along with their foreign medical colleagues, be able to guide the deliberations of the Conference into the proper channels, and thus secure satisfactory results in framing measures for combating the opium habit in all civilised countries as well as in the Far East.

THE new British Sanatorium for consumptive patients built at Davos under the patronage of Queen Alexandra was opened for their reception last week. There is at present accommodation for 54 patients.

³ Cannon: American Journal of Physiology, 1907, vol. xx., p. 283.

Annotations.

"Ne quid nimis."

THE LATE DR. DALLINGER.

THE death of Dr. Dallinger, F.R.S., has brought into renewed prominence the name of a remarkable man who for some time past has been living withdrawn from public notice, but whose career at the period of his greatest activity brought him much into the arena of scientific discussion and into still greater publicity in the character of an expositor of popular science. Ordained a Weslevan minister he became fascinated by the problem of the origin of life at the time when Darwin's work was fixing public attention upon what must always be the most profoundly interesting of scientific problems. Hundreds of minds were stirred by the new interest awakened by Darwin's writings. but with Dr. Dallinger the interest proved to be more than a mere diversion, it gave a colour to his whole thought and direction to his entire career. Less suspicious than most of his professional brethren, he brought an open mind to bear upon the theory of evolution and entered with zeal into the discussion upon scientific lines of the hypothesis of spontaneous generation. Experiments conducted on the lines of Professor Tyndall's famous tests with optically pure air led him, as they had led his teacher, to the conclusion that life is always, under experimental conditions, derived from antecedent life, and he entered the lists as an opponent of the theory which would derive the organic, in its origin as in its sustentation, from the inorganic world. About the same time he formed the ingenious plan of putting the proof of the modification of the living organism by its environment into an experimental form by training certain selected infusoria to adapt themselves to a vast change in the temperature of the medium in which they had their being. Starting with a normal specimen of Tetramitus rostratus and two other infusorial forms, he kept the stock under observation for a period of nearly seven years, and during that time he gradually raised the temperature of the nutrient medium which they inhabited from the ordinary temperature of the atmosphere to a temperature of 158° F. The infusoria adapted themselves, at certain points with great difficulty but eventually with complete success, to the change, and ultimately Dallinger obtained by cultivation varieties which flourished under conditions of life instantly fatal to the unaltered organisms of the original stock, while they themselves had become incapable of returning to the original habitat. This was the work which secured for Dallinger the warm recognition of scientific men. With the general public he obtained even greater credit for the felicitous way in which he presented the more picturesque aspects of natural history to popular audiences, his lectures on the spider in particular having long enjoyed a great vogue. Dr. Dallinger's scientific work was crowned by the editing of Carpenter's book upon the Microscope, a work of large range and real utility, which, without any pretension to great accuracy, presents an extraordinarily comprehensive view of a very large and very complicated subject, and exhibits on every page the impression of a mind trained by long labour and informed by close and continuous contact with the facts discussed. Many books upon the microscope have appeared since the seventh edition of Carpenter's work, which Dr. Dallinger completely revised and largely re-wrote, but no later book has superseded it. It still holds the field as the vade meoum of the British microscopist, and seems likely long to continue so to do, and to sustain the reputation for

extended knowledge and laborious industry of its distinguished editor.

THE ECONOMY OF INSULATION.

THE amount of heat wasted in domestic service is enormous, and the fact is well worth the attention of engineers. Now and then there is evidence of some attempt having been made to prevent this wastage, but the result, generally speaking, has not been very satisfactory. And yet if insulation could be secured with any measure of success a continuous supply of hot water in the house, even through the night and until the fire is lighted again in the morning, might be at hand. In severe wintry weather, just when hot water is wanted most, the wastage is greatest, and the reservoir which was full of water not far from boiling-point just as we retired to our beds is stone cold in the morning, and the re-heating by the re-lit fire is often a slow process. And yet insulation can be made so perfect on a small scale that a single gas flame will eventually melt platinum, the heat being stored up until it reaches the required intensity. If this principle could be put into practice in our dwelling houses there would be a considerable saving of fuel and heat, and hot water would be available continuously. Great care is taken to insulate the electric wire to prevent leakage of the current, and it is surely an anomaly that similar steps cannot be put into practice in the case of the hot water supply. The undoubted advantages offered should induce some serious attention being given to the subject. The vacuum-jacketed flask, known as the thermos flask, is a good and familiar example of the economy of insulation, and though this method would scarcely be practicable on a large scale there must be other methods which could be made applicable to domestic heating apparatus. This way lies a fortune for the inventor, while the problems ought not to defy ingenuity.

COURAGE AND MEDICINE.

Socrates was of opinion that courage was a preservative against the plague, and he took his walks abroad in Athens during the period of the great epidemic described by Thucydides. The famous Diemerbroeck constantly visited the plague-stricken people of Nimeguen and yet escaped contagion. The manner, indeed, in which medical men have in all ages remained free from infection is one of the puzzles of medical history. Cynics might be inclined to say that chance has at all times had a good deal to do with medical immunity, and that a prosaic habit of mind, which is tantamount to lack of imagination, has been a great help-meet to mere fortuitousness. A kindlier view is that which attributes immunity to moral courage and which recognises in the medical man the pre-eminently plucky individual. Some 90 years ago Campardan of Gers collected some interesting instances of courage exhibited by medical men and by their patients. His book, "Du Courage dans les Maladies," was awarded a prize by the authorities of the Hôpital Saint-Louis, but its subject-manner is often not such as to commend it to the jealous stickler for medical ethics. It would appear, indeed, according to Campardan, that some of the greatest physicians have gone perilously near sheer quackery when appealing to their patients' fortitude. Thus the celebrated Dessault was not above pretending to cut for stone in the case of a Parisian wigmaker, who in his turn pretended not to be afraid of the operation. Dessault saw that the man, who fainted under the knife, would die if actually operated upon. He therefore, when the man came to, showed him a calculus which he said he had extracted from the bladder, but had really picked up from the table close by. But the patient

died under the impression that he had been cut for stone. Pious deception was part of the stock-in-trade of many otherwise most respectable physicians a century ago. Thus Desgenettes, médecin en chef of the army of the East in Napoleon's time, was of opinion that the word peste had better never be mentioned to troops exposed to the infection of plague. But in order to deceive his soldiers and to make them believe that they ran very little risk of infection, he went so far as to dip a lancet into pus from a plague-bubo and to puncture himself thoroughly therewith in the region of the arm-pit. On another occasion, in order to reassure a patient, presumably ill of plague, he drank out of that patient's glass. Was this legitimate courage? "Had I to paint the virtues of the good physician," says Campardan, "I should say 'Medicus est vir probus medendi peritus!'" "Woe unto him," he adds, "who should be satirised by the phrase." It is curious to note how opinion on the ethics of treatment has changed during a century.

MOUTH DISINFECTION.

MUCH attention has of late been directed to the importance of oral sepsis in many cases of chronic ill-health, and much work has been done which has shown the importance of mouth disinfection, without, however, indicating precisely how that disinfection is to be secured. Every practitioner has had cases of pyorrhœa alveolaris, or of persistent infection of the throat by the diphtheria bacillus, in which he has longed for some means by which the resistant microbes may be destroyed, but in which his efforts have proved unavailing. The problem of mouth disinfection is one of great difficulty owing to the large number of microbes present (according to Dr. Piasecki 1 cubic centimetre of saliva may contain 30 to 35 millions of organisms), because of their constant renewal, and on account of the steady withdrawal in the saliva of any drug employed for their destruction. Experience has taught that the value of an antiseptic must be gauged in the conditions which obtain in actual practice, when there are likely to be enormous difficulties in arriving at trustworthy conclusions. In the mouth the problem is complicated by two factors: first, the wide variations in the number of organisms present in normal saliva; and, secondly, the fact that these wide variations may occur rapidly within periods which are not greater than those involved in the experiments for the determination of the disinfection value of a drug. According to the experiments of Dr. Piaseeki, the organisms may be from 20 to 30 times as numerous on some occasions as on others, and many increase as much as 10 times during the period of an hour or two. It is necessary, therefore, to determine a normal bacteria-rate for the saliva of the subjects of an experiment in oral disinfection. A short time ago 1 Dr. Meredith Young, with the assistance of the Manchester Public Health Laboratory, investigated this problem and concluded that formamint lozenges were both an agreeable and efficient means of mouth disinfection, especially in young children. Dr. Piasecki in his paper in THE LANCET of Nov. 6th (p. 1373) has reinvestigated, with different technique and with due regard to the difficulties mentioned above, the value of formamint and of pyocyanase. He finds that formaldehyde in the saliva in such concentration as would result from the sucking of formamint lozenges diminishes the number of organisms present, but hardly to an extent to which any practical value can be attributed. We know, however, that formalin with glycerine swabbed on the tonsil is a very efficient remedy in tonsillitis. Pyocyanase, which is a mixture of proteolytic enzymes obtained from cultures of the bacillus pyocyaneus

and which is used as a spray, was also examined, and the conclusion is reached that it developed a greater bactericidal value than other disinfectants, the value of which had been properly investigated. With both formamint and pyocyanase it was found that if used in too large doses there was an increase in the number of organisms. This is explained as being due to injury to the tissues and normal destructive agencies. It is obvious that further investigations must be undertaken before the daily use of an antiseptic mouth wash by healthy persons can be recommended.

ABYSSINIA IN HEALTH AND DISEASE.

"FOR the moment," writes an Italian correspondent, under date, Rome, Nov. 12th, "European interest hovers round the death-bed of King Menelik, and Triple Alliance and Triple Entente are represented in the imperial antechamber of Addis-Abeba. Of these powers Italy is not the least concerned, her recent past and her immediate future giving her special cause for anxiety as to Abyssinian developments. After her great military reverse on March 1st, 1896, at Adua, the country teemed with Italian prisoners of war, many of them on the army medical staff, whose presence proved a double advantage to their captive compatriots, first for professional tendance, and second for the favourable conditions they succeeded in securing from the victor. Skilled in medicine and surgery and animated with the humane spirit of their office, seconded as these were by the kindly courteous address by which Italian medical men maintain the best traditions of the healing art, they devoted their spare hours to attending the native sick and wounded till their services were in request from the humblest of the natives to the most potent of the chiefs. not excluding King Menelik himself. As a result of this volunteered duty the Italian name was not only respected but beloved in a land previously jealous of its intrusion, and the prestige it had lost on the battlefield was more than retrieved in the ambulance and the sick-room. Reinforced by the Croce Rossa Italiana the sporadic efforts of the army medical staff were concentrated and organised into system, and now Abyssinia dates her start on the highway of hygiene and improved medical practice from the victory that, in turn, made her the debtor of the vanquished. For the last eight years Italy has strengthened her Legation with an efficient consultant. from whose observations of the progress of Abyssinia in the prevention and cure of disease the world is indebted for many reassuring details as to the country and its sanitary future. To his most interesting monograph, first communicated to the Italian Geographical Society, and published under the title of 'Medicina Vecchia e Medicina Nuova in Abyssinia,' the reader is referred for a luminous picture of the 'situation' medically considered. Dr. Lincoln de Castro. the consultant in question, has much to tell us of ancient practice among the άμύμονας Αίθιοπη̂ας (Homer's 'blameless Ethiopians'), but of more present interest is his statistical account of the 'movimento sanitario,' illustrated by the reports of the public ambulance, established by Italy, and rapidly resorted to by the natives, the Ras and the other chiefs, culminating in the appeal for its services from the Negus in person. From September, 1901, to Dec. 31st, 1907 (allowing for 10 months during which the ambulance work was suspended owing to absence of the personnel), the cases under medico-chirurgical treatment were 26,145, in addition to which vaccination was practised on more than 3000 applicants. These figures do not include the calls made to the city and its neighbourhood. nor the obstetric assistance rendered, but take cognisance only of the indigenous patient. The resources of the ambulance were freely drawn upon, not only for attendance, but

also for medicaments and surgical appliances, there being no public pharmacy or 'farmacista libero.' Surgical maladies top the list in the proportion of 30.50 per cent.; next come internal maladies (27 per cent.); then venereal and syphilitic (21 per cent.); ophthalmic diseases follow (12 per cent.); and finally cutaneous maladies (9.50 per cent.). Under each head Dr. Lincoln de Castro cites interesting details, variegated with picturesque 'objectlessons' in faith-healing, which has its votaries in Abyssinia dating from 'hoary tradition,' much more to be excused for their credulity than the twentieth-century fanatic who sins in the face of science and expert opinion. Parasitic disease is common—it being 'no disgrace for an Abyssinian to be filthy and lousy-all the more if he is in mourning, in which case dirt is the synonym of dark or sadcoloured.' A woman dressed in clean garments, according to Dr. Lincoln de Castro, is looked at askance 'because this laudable habit (that of being decently attired) is the prerogative of the "sciarmute," or priestesses of Venus. On malaria, which numbers victims at altitudes of 7000 feet and more, the monograph is specially illuminating; not less so the sections dealing with helminthology, a subject in which Abyssinia has a traditional interest. For the tænia solium and the mediocanellata, the ascaris lumbricoides and the oxyuris vermicularis the European remedy, ethereal extract of the male shield-fern is the favourite, the native kousso having long given way to it, except in regions beyond the European radius. Many details as to the physique, the diet, the tendency to disease among the indigenous population lend practical interest to Dr. Lincoln de Castro's pages, confirming as they do the salutary effects of the white man's intervention in equatorial or Central Africa-an intervention counselled more than 40 years ago by the Capuchin missionary (afterwards Cardinal) Massaia when in the late 'sixties' of last century he advised young Menelik to throw in his lot with the British expeditionary force under Napier of Magdala and give his country the benefit of an alliance which spells civilisation and progress all the world over."

THE LANCET,]

ANOTHER DIAGNOSTIC APPLICATION FOR LUMBAR PUNCTURE.

FRENCH neurologists have of late paid much attention to a group of changes in the cerebro-spinal fluid withdrawn by lumbar puncture from certain cases of spinal disease. The changes are a yellow tinge, liability to massive coagulation. and the presence of lymphocytes together with red blood corpuscles. This syndrome has been so far identified with two diseases only-sarcoma of the spinal dura mater and a form of meningo-myelitis. Of the three features of the syndrome the last, the cytology of the fluid, is the least constant, and some of those who have investigated the matter have considered that the absence of this feature in cases where colouration and clotting were noted indicated the presence of a new growth rather than of an inflammatory lesion. Mesbrezat and Roger, however, describe a case of meningo-myelitis in a man aged 29 years, apparently free from syphilis, in whom a progressive spastic paraplegia was associated with sensory changes in the lower limbs and partial loss of sphincter control. The cerebro-spinal fluid was drawn off repeatedly by lumbar puncture, and showed on each occasion a tendency to clot and a yellow colour; both these changes varied in degree, but neither was ever entirely absent. The characteristic cytological picture was, on the other hand, more often absent than present. The lesson to be learnt is that the presence of lymphocytes with red corpuscles is an inconstant part of the syndrome, and

that it cannot be used to differentiate between the two lesions with which the syndrome has so far been identified. It is not easy at first sight to see why these changes in the cerebro-spinal fluid should be common to two disorders so widely diverse in many ways, and why in each of these disorders it should only be manifested in certain cases. Mesbrezat and Roger, by reference to those cases in which a necropsy has thrown light on the causation of the syndrome, point out that, whether there be new growth or inflammatory change, there is a more or less complete band of meningeal adhesions encircling the cord, converting the subarachnoid cavity below the lesion into a kind of closed lagoon. Hæmorrhages, however small, into such a space will give the contained cerebro-spinal fluid certain abnormal constituents which cannot undergo reabsorption as they do when blood is shed into the normally drained subarachnoid cavity; the consequence is that pigmentation, a high fibrin content, and red corpuscles with or without lymphocytes, remain indefinitely. The syndrome may therefore be taken to prove that the fluid in which it is manifested has been withdrawn from a portion of the subarachnoid space shut off from the main cavity by inflammatory or neoplastic adhesions. According to Rindfleisch, cells with large nuclei may also be found in such a fluid if it has been withdrawn from a case of sarcoma; if this be so, it should serve to differentiate between the two lesions which have so far been indistinguishably identified with xanthochromia and massive coagulation of the cerebro-spinal fluid.

THE ANNUAL DINNER OF THE SOCIETY OF APOTHECARIES OF LONDON.

As the Master, Mr. R. Bligh Wall, said, in response to the toast of "The Society of Apothecaries," which was proposed by the Lord Mayor, after the "Lord Mayor's Day" dinner held at Apothecaries' Hall on Tuesday evening, those gatherings are of particular interest in that they afford a meeting-ground for the ancient and honourable traditions of English medicine with the even more ancient and no less honourable traditions of the Livery Companies of the City of London, and this year's reunion of medical men and civic worthies was in every way worthy of its predecessors. The dinner was excellent, the speeches were admirably short (being finished almost by 10 o'clock), and some very pleasant vocal music, which included the "Laudi Spirituali" grace, was all in keeping with the prevailing spirit of hospitality. After the loyal toasts, the Master proposed "The Lord Mayor, Sheriffs, and Corporation of the City of London," which was responded to by Sir John Knill. Mr. A. T. Norton, the Senior Warden, then gave "The Royal Colleges of Physicians and Surgeons," to which their respective Presidents replied, Mr. Butlin receiving a particularly hearty greeting, as it was the first time he had dined in the hall invested with his present dignity. The Senior Warden referred to the necessity of action on behalf both of his own Society and of the English Royal Colleges in the present crisis if they were not to lose their examining functions, and advocated the establishment of a State University of Medicine as the single method of entering the profession. Richard Douglas Powell, however, pointed out that a one-Faculty University was a contradiction of terms, and that the Royal Colleges were doing their utmost to bring about a working arrangement with the University of London under which their diplomates would become available for a medical degree. The toast of "The Visitors" was proposed by Mr. E. Parker Young and replied to by the Master of the Skinners' Company. Amongst the guests present were Mr. Sheriff Roll, Sir Clifford Allbutt, Sir William Church, Alderman Sir Thomas Crosby, the Master of the Skinners' Company, the Master of the Drapers' Company, the Master

of the Haberdashers' Company, Dr. F. H. Champneys, Mr. J. T. Helby, Chairman of the Metropolitan Asylums Board, Rev. Canon Morris, Mr. Hugh Davies, Sir Shirley Murphy, Sir Hugh Beevor, Bart., Dr. Lewers, Mr. Arbuthnot Lane, Fleet-Surgeon H. W. Macnamara, Dr. Leonard Hill, and the representatives of the *British Medical Journal* and THE LANCET.

INTERSTICE AND CREVICE.

It is not difficult to present cases which prove that the interstice and the crevice can be enemies of health. The man who allows particles of white lead to accumulate and to stay beneath his finger-nails sooner or later suffers from lead poisoning. To him the frequent application of the scrubbing brush may make all the difference between health and disease. The neglect, again, to remove particles of decaying food lodged between the teeth may well give rise to a septic process. Once more the brush must be brought into hygienic service. As is well known, a factor of no little importance in infant feeding is the use of a bottle which can be easily and scrupulously cleaned and which contains, therefore, no crevices which make the cleaning process difficult and which harbour pabulum and provide a breeding ground for disease-producing organisms. The interstices of the common dining fork are similarly hygienically objectionable and require careful attention when the fork is cleaned. The moustache cup is an abomination, the inside surface of the guard being almost inaccessible for cleaning purposes, and the hollow-stemmed wine glass presents a similar objection. Hygienic practice suggests, in fact, that all articles in domestic use which are difficult to clean because of interstice and crevice should be banished. This tenet, however, may more reasonably be supported in the case of articles intended to convey food than in the case of other articles, as, for example, clothes. It would be difficult, for example, to abolish the interstices and crevices of our boots, and yet we have it on scientific authority that the boots of the Members of the House of Commons may be a contributory factor to the seasonal prevalence of influenza in that place. It would appear ridiculous to suggest that the boots be left outside the portal of our homes and offices, although that would clearly be a real remedy which no amount of cleaning on a mat can ever be. The interstices of the outdoor garment obviously afford excellent lodgement for micro-organisms and dust, which the application of the clothes-brush proves day by day, but clothes should be brushed out of doors. There are cases in which the dangers of the interstice and crevice can be avoided. and where they cannot they can be minimised by a regard for cleanly practices.

UTERINE CRISES IN TABES DORSALIS.

REFERENCE was made in these columns some months ago to the extensive field of operation of the pathological process underlying tabes dorsalis, and an illustration was afforded by certain affections of the nose of an obscure nature which on examination turned out to be nasal crises, indicative of a more serious systematised disease of the spinal cord. The importance of the subject from the diagnostic and therapeutic standpoint may be further illustrated by a glance at a communication from Dr. Franz Conzen of the Polyclinic in Leipzig, which appeared in the Neurologisches Centralblatt for January of this year. A healthylooking married woman, aged 33 years, came to the Clinic complaining that for some months she had experienced labour pains although she was not pregnant. It appeared that during her menstrual periods, which were quite regular, but solely on the one or two days when no discharge was visible,

she was attacked by recurring pains, which felt exactly like those she had already experienced at her confinements, pains which seemed to be localised in the uterus and were accompanied by swelling and muscular contractions of the abdomen. In the course of two or three minutes they became unbearable, and at the height of the paroxysm she had a distinct sensation as though the child's head were passing through and distending the vagina. The total duration of these attacks was about four minutes, and they were always followed by general muscular trembling, especially of the lower extremities. The fact that the patient also complained of lightning pains in the limbs was significant, and careful examination revealed double Argyll-Robertson pupils and absent Achilles-jerks, though the knee-jerks were present. The diagnosis of tabes dorsalis was clearly correct. Visceral crises involving the uterus are not unknown. Abadie has described a case of "crises douloureuses de faux accouchement chez une tabétique." They are, however, probably very uncommon. The seat of the pathological process is the eleventh and twelfth dorsal segments of the cord, whence is derived both the motor and the sensory innervation of the uterus. The complex nature of the sensations thus aroused and referred to the uterus and vagina is of considerable interest from a psychological point of view. Muscular trembling during labour, a phenomenon reproduced in these uterine crises, is well known as a normal occurrence; it has been dignified with the name of "dolores conquassantes."

VOLUNTARY WITHDRAWAL FROM THE MEDICAL REGISTER.

WE publish in another column under this heading an interesting letter from a correspondent who quotes the recent decision of the General Medical Council in the matter and invites us to consider that the proposed standing order leaves both the Council and the medical profession insufficiently protected. We think that there may be ground for suggesting that the whole question should be reconsidered afresh, for undoubtedly there are the objections to voluntary withdrawals from the Register. even when no charge is officially known to be pending over the applicant's head, to which our correspondent has drawn attention. The standing order already drafted may be regarded as quite satisfactory so far as it goes, but does it go far enough? Should it be supplemented, for example, by a further order, under which the Council could satisfy itself not only that nothing is known of a kind detrimental to the professional morale of the applicant, but also that in his case there are circumstances exceptional and peculiar to himself which make it quite natural that he should wish to disappear from the Register? Liberty is a great thing, and we hesitate before setting any bounds to it, but it is impossible not to see that an unscrupulous person might do harm by continuing to practise medicine after withdrawal from the Register. He would be a fully qualified practitioner in the ordinary sense of the term, but free to practise on ethical lines totally contrary to the Council's view of right conduct, or to trade upon his possession of medical knowledge and medical diplomas in some other fashion equally detrimental to the true interests of the public. And it is to be remembered that if voluntary withdrawals from the Register are facilitated and the fashion is allowed to become prevalent, inextricable confusion will be set up between these withdrawals and penal erasures. In other words, the sole weapon which the Council possesses against deliberate offenders will be deprived of half its force. We do not think it would be quite as simple as our correspondent appears to believe for the General Medical Council to resist the wishes of a registered medical man to

cease from registration; but his letter brings some important points forward, and the General Medical Council will, we hope, debate them.

DOUBLE RESECTION OF THE INTESTINE.

REMOVAL of a portion of the bowel is now almost a commonplace in surgery, though opinions are still somewhat divided as to the best method by which the two ends of the intestine should be united. A very large number of methods have been devised for this purpose and many ingenious mechanisms have been invented to assist the surgeon, but experience seems to show that the more practice the surgeon has in performing this operation the less is he inclined to rely on these mechanical aids. At present, however, it is somewhat rare for resection of bowel to be performed more than once in the same patient, and therefore the cases recorded in the present number of THE LANCET by Mr. Hugh M. Rigby are of special interest. In the former of these cases the patient, a woman, 31 years old, had a piece of the large intestine removed for carcinomatous growth, and a year later another portion was removed for a recurrence of the growth. In the second case a boy, 9 years old, suffered from internal strangulation by a band which caused gangrene of a portion of the lower ileum measuring 24 feet in length. Mr. Rigby excised this and sutured the ileum to the cocum by lateral anastomosis. A focal fistula followed, the skin wound giving way, and it was resolved to short-circuit the affected portion of the bowel so as to divert the stream of fæcal matter. This was done, the small intestine being divided above its junction with the cæcum; the proximal portion was united by a lateral anastomosis to the transverse colon, and the lower portion of the bowel was invaginated and closed. Later it was decided to excise the short-circuited portion of the large and small intestine, the skin surrounding the facal fistula being removed at the same time. The portion of bowel excised in the second case comprised the hepatic flexure of the colon, the ascending colon, the cæcum, and the attached portion of the ileum. In this case also success followed the operation. We think that Mr. Rigby is to be congratulated on the results of these two cases, and they demonstrate the comparative safety with which extensive portions of bowel can be removed when due precautions are taken. In the second case the excision of so much intestine for the cure of a fæcal fistula is somewhat unusual, but in the circumstances it was fully justified. For the full appreciation of the difficulties of the cases, and of the methods in which those difficulties were met, it is necessary to read Mr. Rigby's paper.

By an inadvertence the name of Mr. Henry William Newton, L.F.P.S. Glasg., who has been the recipient of a knighthood, was omitted from the list of Birthday Honours which we published last week. Sir Henry W. Newton was born in the year 1842, his father being a well-known medical practitioner in Newcastle. He is the "father" of the city council, having entered that body in 1866. He has been a sheriff of Newcastle and has twice held the office of mayor. As a member of the city council he has done excellent work in the interest of the public health, and a few years ago his fellow citizens showed their appreciation of his labours by presenting him with the freedom of the city. We congratulate him in the name of the profession upon the well-deserved honour of knighthood.

THE death is announced of Mr. Michael Castaneda, M.B. Lond., M.R.C.P. Lond., formerly physician to the Spanish Embassy and Italian Consulate, and senior consulting physician to the Italian Hospital in Queen-square.

In connexion with the visit of the King of Portugal to this country His Majesty the King has conferred upon Dr. de Mello Breyner, Physician in Ordinary to King Manuel, the Companionship of the Royal Victorian Order.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies stated that 21 cases of plague with 12 deaths were reported on Nov. 12th.

Major Ronald Boss, F.R.S., has been awarded a Royal medal by the Royal Society in recognition of his researches in connexion with malaria.

THE Asylum Officers' Superannuation Bill has received a third reading in the House of Lords.

BRITISH MEDICAL BENEVOLENT FUND.

At the October meeting of the committee 27 cases were considered and grants amounting to £246 made to 22 of the applicants. Appended is an abstract of the cases assisted :--

applicants. Appended is an abstract of the cases assisted:—Widow, aged 40 years, of M.R.C.S., L.R.C.P. Quite unprovided for at husband's death, and at present, owing to a nervous breakdown, is incapable of supporting herself. No children. Voted £10.

Widow, aged 61 years, of M.R.C.S., L.S.A. Practically unprovided for at husband's death a few years ago, and has failed to maintain herself by taking boarders. Children only able to give very slight help Voted £12.

Widow, aged 42 years, of F.R.C.S., who was for many years a teacher at a London medical school. Since husband's death has supported the reself by letting lodgings or acting as housekeeper, but was compelled to give up her last post on account of ill-health. Now proposes to start a small tea-shop. Three children, all in institutions. Voted £15.

Widow, aged 41 years, of L.R.C.S., L.R.C.P. Irel., who practised is West Africa. Quite unprovided for and endeavouring to obtain boarders or lodgers. Four children, of whom two are still at school.

boarders or tougets. About Voted £10.

M.R.C.S., L.S.A., aged 84 years, who practised in London. No income. Children only just self-supporting; receives a little help from relations. Voted £12.

Widow, aged 69 years, of M.R.C.S. Only income £10 a year, and has been admitted by her daughter, whose earnings have so much decreased.

been assisted by her daughter, whose earnings have so much decreased that the help has to be withdrawn. Relieved four times, £50. Voted

been assisted by her daughter, when help has to be withdrawn. Relieved four times, £50. Voted £12.

Widow, agod 55 years, of L.S.A. No income, and dependent on a son earning 55s. a week. Relieved eight times, £90. Voted £12.

Daughter, aged 41 years, of late F.R.C.S. Quite unable to carn a living owing to continued ill-health, and dependent on her mother whose income is £30 a year. Relieved nine times, £84. Voted £12.

Widow, aged 42 years, of L.R.C.P. Edin, M.R.C.S. Quite unprevided for at husband's death from new growth a year ago, and endeavours to support herself by letting lodgings. Slight help from a stepson in the Aferchant Service. Relieved once, £12. Voted £12.

Widow, aged 52 years, of M.B., C.M. Aberd. Income £19 a year and makes a few shillings a week by taking boarders. Three children still at school. Relieved twice, £15. Voted £5.

Widow, aged 62 years, of L.R.C.P. Edin., M.R.C.S. Eng. Is helped by her daughter, a governess, and earns a little by teaching. Relieved 11 times, £37. Voted £5.

Daughters, aged 45 and 37 years, of late L.S.A. Both unable to earn a living on account of persistent ill health. Relieved five times, £30. Voted £12.

Widow, aged 60 years, of M.R.C.S. No income; a few shillings a most allowed by children. Health too feeble to permit of occupation.

Voted \$12.

Widow, aged 60 years, of M.R.C.S. No income; a few shillings a week allowed by children. Health too feeble to permit of occupation. Relieved 11 times, £123. Voted £12.

Daughter, aged 69 years, of late M.R.C.S. Lost her fatner when 3 years old, and has supported herself since the age of 17. After being a governess for many years, took a house and received boarders, but has recently found herself unable to meet expenses. Relieved twice, £19. Voted £5.

Daughter, aged 57 years, of late L.R.C.P., L.S.A. Being very dea and incapable of earning a living is dependent on a sister, a menta nurse, who is unable to earn as much as formerly. Relieved four times? £44. Voted £12.

nurse, who is unable to earn as much as formerly. Relieved four times £44. Voted £12.

Widow, aged 53 years, of M.R.C.S., L.S.A. No income; no children; health very feeble. Relieved six times, £56. Voted £12.

Daughter, aged 38 years, of late F R.C.S. No income, and owing to tuberculous disease of a large joint is only able to do light work occasionally. Receives a small weekly allowance from another charity. Relieved three times, £36. Voted £12.

L.R.C.P., L.R.C.S. Edin, aged 74 years. Has been unable to practise for some years past owing to deafness and ill-health, and is now practically dependent on friends. Relieved three times, £29. Voted £12.

M.D. Aberd., aged 57 years. Is quite incapacitated by lateral sclerosis. Only income two small pensions from charities. Two children, both still at school. Relieved once, £10. Voted £18.

Widow, aged 64 years, of M.R.C.S. Owns a small property in Ireland, but the income has now diminished to a few shillings a week. Children just self-supporting. Relieved ten times, £32. Voted £10.

Daughter, aged 60 years, of late M.R.C.S. No income; slight help from friends. Barns a few pounds yearly by knitting. Relieved five times, £54. Voted £12.

Widow, aged 69 years, of M.D. St. And. Being unprovided for

willow, aged 69 years, of M.D. St. And. Being unprovided for at husband's death established a home for invalids, but was unable to meet expenses; is now dependent on occasional help from friends. Relieved twice, £30. Voted £12.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

THE STANDARDISATION OF DISINFECTANTS.

WITH SPECIAL REFERENCE TO THE DISINFECTANT PREPARATIONS COMMONLY SOLD TO THE PUBLIC.

A CHEMICAL AND BACTERIOLOGICAL INQUIRY.

SECTION II.*

THE BACTERIOLOGICAL EXAMINATION OF CERTAIN DISINFECTANTS.

PART I.—BACTERIOLOGICAL METHODS OF ESTIMATING THE GERMICIDAL EFFICIENCY OF DISINFECTANTS.

No satisfactory method of estimating the comparative germicidal efficiency of different disinfectants, under the varying conditions met with in actual practice, has as yet been devised. The conditions existing in practical disinfection are so numerous and vary so greatly that any single method hitherto suggested fails to meet more than a small proportion of them.

The more satisfactory standard by which to compare one germicidal substance with another is, of course, the comparative power that each possesses of destroying the vitality of a specific micro-organism. Chemical analysis, up to the present, has certainly failed to provide us with any means of determining the true value of a disinfectant, and it was assumed that this was because the problem was physico-chemical, rather than one of pure chemistry. Until the exact chemical composition of the various disinfectants is known and the germicidal value of their constituents is determined, and until, moreover, a definite understanding of the actual germicidal activity of a disinfectant in relation to its chemical and physical composition is arrived at, a chemical analysis, made with the object of estimating the germicidal properties of a disinfectant, must be comparatively valueless. With such knowledge, however, the chemical method may assume far greater importance than it now possesses.

It must be admitted that the bacteriological tests which have been used up to the present are too narrow to include many of the factors which must influence, advantageously or prejudicially, the bacterioidal power of the disinfectant. Amongst such factors may be reckoned the character of the micro-organism to be destroyed; the chemical and physical nature of the fluid medium or nidus in which it exists; the temperature at which the disinfecting process is carried on; the time during which the disinfectant is allowed to act; and the fluid with which it is diluted—distilled water, hard water, sea water, &c. In any experimental test an attempt should be made to introduce those factors which may be supposed to influence the process of disinfection as carried out under natural conditions, but these are so varied in character and degree that it would seem almost impossible to include them all. Some work has already been done in this field of investigation, but much still remains to be accomplished.

The earliest observations of which we have any record are those of Sir John Pringle (1 and 2), who in 1752 described a series of experiments "for making standards whereby to judge of the septic or antiseptic strength of bodies." Taking sea salt as his unit he worked out what might be described as a "sea salt coefficient" for several chemical substances. During the next hundred years numerous experiments with disinfectant substances seem to have been conducted on similar lines. In 1875 Buchanan Baxter (3 and 4) carried out a series of investigations on the action of certain disinfectant materials on impure cultures. Amongst his conclusions

were the following: that "antiseptic" is not synonymous with "disinfectant" power; that the medium in which the infective particles are distributed in disinfection by such substances as potassium permanganate and chlorine is of prime importance, and that no virulent liquid can be considered disinfected by carbolic acid unless it contain at least 2 per cent. of the pure acid. Jalan de la Croix (5), working along similar lines, studied the influence of the medium in which the disinfecting action occurs; he also recognised the importance of the greater resistance of spores.

With the introduction of pure cultures, as obtained and used by Koch (6), experiments were carried out which, although characterised by greater scientific accuracy, were lacking, perhaps, in those broader features of the older and rougher experiments, which caused them to conform more closely to the conditions that would be met with in practical disinfection. In these experiments, made in 1881, he used cultures of B. prodigiosus, B. pyocyaneus, and B. anthracis (both free from spores and as sporing forms); he soaked threads in a culture of the special organism, and afterwards dried them and exposed them for various periods to the action of the disinfectant to be tested. These threads were then washed and arranged at intervals on the surface of a solid nutrient medium and incubated to see if growth occurred alongside them. The use of the solid medium had the disadvantage that the remains of the disinfectant tended to adhere to the bacteria and to prevent growth, instead of being immediately dispersed and diluted as would be the case if the thread was introduced into a fluid medium. In 1887, to get over this difficulty, one of us (7) used silk threads which, after being thoroughly dried, were soaked in a culture or emulsion of a micro-organism, with or without These threads were then placed for varying periods in solutions of different strengths of the disinfectant They were then thoroughly washed to be tested. in distilled water to remove such of the disinfectant as had not been fixed; the threads were then trans-ferred to a fluid nutrient medium. Accounts of similar experiments were published by Fraenkel in 1889 (8) and in 1890 by Behring (9). In 1888 Sternberg (10) described a method he had used in 1880: "The time has been constant -usually two hours-and the object has been to find the minimum amount of various chemical agents which would destroy the test organism in this time. A certain quantity of a recent culture, usually 5 cubic centimetres, has been mixed with an equal quantity of a standard solution of the germicidal agent. Thus 5 cubic centimetres of a 1 in 200 solution of carbolic acid would be added to 5 cubic centimetres of a recent culture of the typhoid bacillus, for example, and after two hours' contact one or two loopfuls would be introduced into a suitable nutrient medium to test the disinfection. In the case in question the results obtained would be set down as the action of carbolic acid in the proportion of 1 to 400." This was evidently the predecessor of the drop method.

The next modification was that involving the use of a small quantity of bacterial emulsion made either from a broth oulture or from a gelatin or agar culture emulsified in distilled water, with a large quantity of the disinfectant, thus reducing to a minimum the amount of foreign material in the mixture. In 1886 Wynter Blyth (11) added measured quantities of emulsion in distilled water to known quantities of the disinfectant, and, after allowing this disinfectant to act for a given time, he transferred a drop of the mixture to melted gelatin, thus plating it out by Koch's isolation method. Krönig and Paul in 1897 (12) adopted an entirely original plan. They coated small garnets of uniform size with an emulsion in water of a culture containing sporulating anthrax bacilli. These were then dried and exposed to the action of the disinfectant solution. They were then rinsed and the organisms after being washed off into sterile water were plated and counted. Their experiments led these observers to consider the action of disinfectants upon bacteria, as a chemical reaction between the bacterial In 1897 Defries (13) protoplasm and the disinfectant. allowed small measured quantities of broth culture to dry in thin films at the bottom of test-tubes. Disinfectant dilutions were then added and allowed to act for certain times. They were then poured away, and after each tube had been rinsed culture medium was introduced; in this the organisms surviving in the film could grow. In 1903 Rideal

^{*} The parenthetical figures occurring throughout this Section have reference to the bibliography at the end of the Section. The first Section was published in The LANCET of Nov. 13th, 1909, p. 1454.

number of factors concerning which we have at present no accurate data. Chemical methods, by themselves, have hitherto given us little or no light on any of the points that have to be settled, and the information derived from the application of bacteriological methods is essentially sketchy and incomplete.

Of all bacteriological methods yet published the Rideal-Walker method has obtained the greatest vogue. sight it appears simple to carry out and if successful it gives definite information on certain points; it has been officially adopted by Government departments and many makers now state the "carbolic coefficient" figure of their special brand of disinfectant in their advertisements and on the labels on the bottles. Many sanitary authorities have fixed the price per unit of coefficiency as found by their analysts as the basis on which to buy disinfecting fluids for use in public We decided, therefore, that in order to departments. make a preliminary comparison between the members of any series of the disinfectants in common use we should, in the first instance at any rate, have to utilise the Rideal-Walker method as the one that was in most general use and the one that would give results most likely to be generally understood and therefore likely to meet most the immediate practical requirements of the employer of disinfectants on a large scale. We had previously employed this method sporadically, with somewhat disappointing results, but we realised that some practice might be needed to perfect the manipulation of a method in which much must depend on the acquisition of a certain degree of technical skill by anyone attempting to put it into practice. The results of our more prolonged and continuous series of experiments were again disappointing. Though the experiments were conducted with due care, and the details of the method, as described from time to time by the authors, were followed as closely as possible, the tables of results showed many discrepancies; not only did tubes show growth out of their natural sequence of time and dilution, but when coefficients were calculated at the nearest estimate the coefficient figure so obtained for the same sample of disinfectant varied so much, that it became clear to us that in our hands, at any rate, this was not a satisfactory method for the present purpose.

After four months' practice with the modified method, hereafter described, we again took up the Rideal-Walker method with the object of determining whether, with the further dexterity and technical skill we had acquired, we were able to obtain better results, and, incidentally, of making out if possible wherein lay the cause of the considerable difference which undoubtedly obtained between the coefficients claimed by the manufacturers and the figures we obtained by our modified method. In the series of experiments devised to test these points the same disinfectant was taken on each occasion, and this time the method as described in "The Bacteriological Examination of Disinfectants," by William Partridge, was followed in every detail. A series of 11 consecutive tests were made. From the results of these tests it was possible to obtain definite coefficients in three instances only; in these three instances the coefficient varied within very narrow limits—between 8.1 and 8.5—figures which corresponded very closely with the results obtained by the use of the modified method we had used in the rest of our experiments. Amongst the remaining eight experiments it was possible to obtain two very doubtful coefficients, which might be read according to the bias of the observer. The other six provided little information of any kind. On examining this series of tests and our other experiments carried out by the Rideal-Walker method, and comparing the results obtained from them with those obtained by our modified method, we gained the impression that the high carbolic acid coefficients (20 to 40, &c.) claimed by manufacturers, and often set out in strong contrast to the coefficient allowed by them for the disinfectants manufactured by their rivals, are only to be explained on some such grounds as the following:

1. A standard organism not having been decided upon and different disinfectants reacting differently towards different types of organisms, each manufacturer naturally chooses the coefficient found with the organism which gives the highest figures to his own fluid. Major C. E. P. Fowler (19) tabulates a series of coefficient figures obtained with a well-known disinfectant acting upon different organisms from which we getter that acting upon healths.

and Ainslie Walker (14) introduced a method by which they proposed to determine, and to state in definite numerical terms, the value of any disinfectant. Using carbolic acid as a standard, they classified other disinfectants as having certain units of coefficiency in terms of this acid. They laid down certain standard conditions as being essential to the attainment of successful results by this method. Carbolic acid of known strength is to be used; cultures are to be grown in definite media and for a definite time (24 hours). Loops used for inoculating the organism must be of standard size, and all apparatus should Taking the disinfectant to be tested, four different dilutions of suitable strength are made. A carbolic acid control, or standard, of a suitable dilution is also prepared. A volume of five cubic centimetres of each of these dilutions is introduced each into a sterile test tube. drops of an emulsion of bacteria are taken from a filtered 24 hours' growth of B. typhosus in broth of a standard formula, and introduced at half-minute intervals into the five tubes of the disinfectant. At the end of $2\frac{1}{2}$ minutes a sample of each of the mixtures is taken in a platinum wire loop and introduced into a test tube containing five cubic centimetres of sterile broth. Half a minute is thus allowed for this process for each tube and the tubes are inoculated in the same order as that in which the emulsion was transferred to the antiseptic. This procedure is repeated after 5 minutes, 7½ minutes, 10 minutes, 12½ minutes, and 15 minutes. The broth tubes thus inoculated with "the sample" are put to incubate at blood heat for 48 hours; they are then examined for growth.

The results of this examination may be charted, and if suitable dilutions have been chosen the comparative germicidal properties of the disinfectant of unknown strength and the carbolic acid of known (standard) strength may be seen at a glance and a numerical coefficient of the disinfectant, to carbolic acid taken as unity, may be deduced; for example:—

TABLE II.—Baoillus Typhosus, 24 hours' Broth Culture at 37°C., Room Temperature 68°F. (19/8/09).

Dis- infectant.	Dilu- tion.		ere e	min xpos lisini	ed t		Subculture.				
iniectant.	tion.	21	5	71	10	121	15	Period of incubation.	Tempera- ture.		
Cyllin	1-1000	+	0	0	0	0	0				
,,	1-1100	+	+	+	0	0	0				
,,	1-1200	+	+	+	+	+	+	48 hours.	37° C.		
,,	1-1300	+	+	+	+	+	+				
Phenol	1-120	+	+	0	0	0	0	l			

+ = Growth in subculture. 0 = No growth in subculture.

From this table it will be seen that cyllin in a dilution of 1-1000 kills bacillus typhosus in 5 minutes, but not in $2\frac{1}{2}$; 1 in 1100 kills in 10 minutes, but not in $7\frac{1}{2}$ minutes. Phenol in a dilution of 1-120 kills the same organism in $7\frac{1}{2}$ minutes, but not in 5. From these figures a coefficient is obtained by dividing the figure denoting the strength of the disinfectant by that giving the strength of the control carbolic acid, which kills in the same time; in this example it is necessary to strike an average between $\frac{1}{1}\frac{9}{2}$ and $\frac{1}{1}\frac{1}{2}$ —that is to say, between $\frac{3}{2}$ and $\frac{9}{2}$ · $\frac{1}{2}$ 8 · 7.

Modifications of the Rideal-Walker method have been suggested and used by several observers, mainly with the idea of attempting to bring the conditions into line with those met with in various disinfecting processes. Foreign substances of standard composition have been introduced into the "mixture." These foreign substances, by their presence during the act of sterilisation, undoubtedly influence the comparative bactericidal power of different types of disinfectants. Walker and Sommerville (15) have suggested the addition of starch, Fowler (16) of urine, Wynter Blyth (17) of milk, Martin and Chick (18) of a 3 per cent. ground and dried-up fæces emulsion. All these observers have found that the introduction of foreign material tends to greatly reduce the bactericidal power of any disinfectant used.

It is evident, then, that any series of experiments devised known disinfectant acting upon different organisms from to determine the exact value of a disinfectant must include a which we gather that, acting upon bacillus typhosus. this

disinfectant is 11 or 12 times as active as carbolic acid; upon staphylococcus pyogenes aureus, nine times; upon bacillus pestis, 34 times; upon bacillus coli communis, 11 · 4 times; and upon meningococcus, 54 times.

- 2. Sufficient care has not been taken to carry out a carbolic acid control for each experiment, and to do this with a freshly prepared sample of carbolic acid of recognised strength. It appears possible to us that some observers have used the same carbolic acid control as the standard for many tests, carried out on different days, and under different conditions, not recognising, for example, the vital importance of such an influence as temperature.
- 3. In some cases observers may have been satisfied to obtain coefficients from results showing irregularities, the bias of the observer tending to lower or raise the coefficient as the case might be.
- 4. Experimental errors generally seem to tend in the direction of raising the coefficient.

With regard to the Rideal-Walker test, then, we came to the following conclusions:—

(1) Accurate results may be obtained.

- (2) To obtain such results great care and attention to detail and constant practice are necessary.
- (3) The test should always be carried out by one who is in such constant practice.
- (4) It should be carried out at a standard temperature, and we suggest that the temperature of the fluids used should not vary more than 3° F. from 65° F. (62° to 68° F.). A water bath may be used for the maintenance of this standard temperature.
- (5) One type of organism should be agreed upon and used in testing all disinfectants required for the same general purposes.
- (6) Where the disinfectant is to be used in plague or cholera centres or for special surgical or other similar work the special micro-organism to be destroyed should be used in the test.
- (7) A carbolic acid solution freshly made up from a sample of known strength must be used as the control in each experiment.
- (8) All the other standard requirements of the method, such as size of loop, special culture medium, age of culture, equality of time intervals, &c., must be rigidly complied with.

Our results closely resemble those obtained by Major Fowler in testing this method on behalf of the Disinfectant Standardisation Committee appointed by the Royal Sanitary Institute (20), and Lieutenant-Colonel Firth and Professor Macfadyen in their report on this investigation appear to have arrived at conclusions very similar to our own.

Our unsatisfactory experiences of the test performed in the orthodox way led us to devise a certain modification by which we hoped to obtain an extended and more definite picture of the comparative germicidal power of disinfectants. These modifications were chiefly concerned with: (1) the number of dilutions employed and the number and duration of the time intervals allowed in each experiment; (2) the organism and the medium used for its sub-culture; (3) the amount of the "sample" of the "mixture" taken after the disinfectant has acted on the micro-organism; and (4) the method of determining the coefficient.

1. The number of dilutions and time periods.—In the first place we increased the number of time periods at which the test was carried out and thus obtained "samples" in which the disinfectant had been acting up to 30 minutes. This, of course, necessitated an increase in the number of dilutions so as to ensure that at the first time period of 2½ minutes and at the last of 30 minutes both positive and negative results might be shown. Between these two extremes a curve indicating the line of demarcation between positive and negative results could thus be drawn.

In most instances the grading of the various disinfectant solutions was by intervals of about 10 per cent., and to keep our curve within the limits of the charted results it was often necessary to work with as many as 12 dilutions—i.e., to incoulate 12 tubes within 2½ minutes. This could not be done in the ordinary way, but was easily accomplished with the assistance of the time-saving device described below.

The carbolic acid was tested side by side with the disinfectant of unknown strength, a corresponding number of dilutions being made in order to obtain the same "curve of demarcation"; this curve could be compared with that obtained with the disinfectant and a coefficient thus deduced. 2. The organism employed and the medium in which it is cultivated.—As most of the disinfectants tested are to be used for sanitary purposes, it seemed desirable to select one of the organisms of the typhoid-colon group on which to carry out the test. The fact that for bacillus coli communis we have a specific culture medium, McConkey's bile salts medium, which by a colour change (blue to red) indicates very clearly the growth of that organism, led us to adopt the bacillus coli communis, with McConkey's medium for sub-cultures, in all our experiments.

The use of the typhoid bacillus is after all merely a fetich giving an undeserved feeling of confidence in the coefficient figure. Without a special reaction, such as that obtained with McConkey's medium, falsification of the results by accidental contamination is very likely to occur. Moreover, there is the additional disadvantage that work with the typhoid organism is attended with unnecessary danger. Bacillus coli communis as a test organism, in addition to the fact that it is slightly, but only slightly, more resistant than the typhoid bacillus to the action of carbolic acid, has the following advantages: (1) it is non-pathogenic; (2) a culture of very constant biological characters may be obtained by carrying on a culture every 24 hours in broth of the same standard composition; and (3) if McConkey's bile salts medium is used for sub-cultures the risk of misleading results from accidental contamination is practically eliminated.

3. The "sample" of the "mixture" taken after the action of the disinfectant on the mirro-organism.—In going over our results obtained by the Rideal-Walker method we came to the conclusion that their irregularity might be due, in part at any rate, to the fact that the loopful of the mixture taken for sub-cultures, being so small, might very easily fail to include any living bacteria when but few remained in the The plating-out experiments of Martin and Chick (18) go to show that in the case where the action of the disinfectant has just failed to prevent growth, this growth is set up by a very few remaining organisms. order, therefore, to take a larger quantity, and so a fairer sample, at each inoculation we made use of small platinum spoons which held at least three times as much as a standard loop; the extra amount of disinfectant conveyed at the same time was immediately well diluted by being shaken in a large quantity (10 cubic centimetres) of the sub-culture medium.

4. The method of determining the coefficient.—Here again we have found it expedient to introduce a modification. In the Rideal-Walker method the carbolic acid coefficient is found by dividing the figure indicating the dilution of the disinfectant by that expressing the dilution of the carbolic acid which takes an equal time to kill all the organisms, the time taken varying from 2½ minutes to 12½ minutes.

In our method we first take the figure representing the percentage composition of the weakest dilution of the disinfectant which kills at 2½ minutes, and divide this by the figure representing the percentage composition of the weakest dilution of the carbolic acid which also kills at 2½ minutes; we thus obtain a coefficient for the 21 minutes period; a coefficient for the 30 minutes' period is obtained in the same way. We then take the mean of these two figures as the true coefficient. The accuracy of the points which provide the data for obtaining our coefficient is confirmed by the regularity of the intervening curves forming the "lines of demarcation." The occurrence of positive results on the negative side or negative results on the positive side may be looked upon as "faults," and these faults, if few in number and obviously of accidental origin, may be neglected. In any case, they cannot influence the result. We suggest that by this method—(1) we obtain a fairer comparison between disinfectants which act quickly and those which act more slowly; (2) experimental error is at once made evident; and (3) a more extensive picture of the germioidal power of a disinfectant is exhibited.

PART II.—THE MODIFICATION OF THE RIDEAL-WALKER METHOD.

The organism for the test.—Bacillus coli communis was used throughout the whole of the experiments; broth was sown and the culture allowed to grow for 24 hours at 37°C. The broth is prepared in the following way. Mince 1 pound of fat-free bullock's heart meat and allow it to macerate in cold water for two or three hours. Cook slowly over a small gas fiame for two or three hours more, then boil and filter, and add water up to a litre. Add 10 grammes each, of sodium

chloride and peptone (Witte), and standardize the broth to an acidity of +1.5 (phenol-phthalein). To obtain an emulsion from the 24 hours' culture, the mouth of the testtube was sealed in a flame, and the tube then well shaken to break up the growth. Lastly, the shaken culture was filtered through a double layer of Swedish filter paper. By these means the larger clumps were eliminated and an emulsion having biological characters as constant as possible was

The carbolic acid used as control.—We made use of samples from a large bulk of absolute phenol, great care being taken that the crystals when weighed should be as dry as possible, since rapid lowering of the percentage by weight of phenol present takes place when deliquescence occurs. The closeness of the results obtained with the various control tests afforded evidence that little or no variation had occurred through any lack of attention to this detail. The original chemical test of our carbolic acid was supposed to indicate that the bulk was of such strength that 1.1 gramme might be reckoned as I gramme of pure phenol; the dilutions were, therefore, made on this basis. More elaborate tests made at a later stage showed, however, that it would be more just to consider that a dry sample of our crystalline carbolic acid consisted practically of 100 per cent. of pure phenol; all our calculations, therefore, have been made on that basis, the formulæ 1·1-100, 1·1-110, 1·1-120, &c., being converted platform and is now cool and ready for use; this occurs each

into percentages in order to express our results in sufficiently accurate figures.

The dilutions were invariably freshly made, as it was found that after 24 hours they lost some of their bactericidal power, even though kept corked and in the dark (see results of

experiments).

The disinfectant dilutions.— These dilutions were made with sterile distilled water; in the case of thick, syrupy disinfectants a quantity of never less than 5 cubic centimetres was taken to make up the stock generally a 1 per cent. solution. From this stock such dilutions were made as broad preliminary tests showed to be necessary. As little delay as possible was allowed between the making of the dilutions and the carrying out of the test. The dilutions chosen, following the Rideal-Walker method, were generally graded so that the increase of water in each dilution was about 10 per

cent. of the amount contained in the strongest—thus, 1-100, 1-110, 1-120, &c., or 1-200, 1-220, 1-240, &c. This gradation, though perhaps the most quickly made, and giving figures in every-day use, introduces a complication which it would be well to avoid; for, as the dilutions get weaker, the intervals between successive dilutions become less, the progression being geometrical instead of arithmetical. We recommend, and in future shall use, dilutions which increase by a regular arithmetical percentage.

Special apparatus used in the method. - To contain the disinfectant dilutions for the purposes of "seeding" bacteria, instead of test tubes, glass specimen pots 2½ inches high and i inch in diameter were used. These were arranged in a row in holes in a wooden board or in a water bath specially prepared to receive them, and though they were left uncovered it was found that the results were not vitiated by contamination owing to the specific composition of the medium used for the secondary cultures. Against each specimen pot was a letter indicating the dilution it contained. For the purposes of "seeding" the disinfectant, and also conveying "samples" of the mixture to the secondary culture tubes, specially constructed platinum spoons were used. To a glass rod was fixed a stout platinum wire, which at its distal end was soldered to the edge of a tiny platinum cup—a half sphere of eight millimetres in diameter. The object of the use of this spoon was to render it possible to convey more fluid at a time than could be carried in an ordinary platinum loop. It was found by a series of weighing experiments that the spoon took up about 0.08 cubic centimetre of water, while a loop would take up less than a third as much. These spoons were made so strong that they could be used as stirring instruments, so that effectual mixing could be ensured at the same time that the material was introduced. As they were somewhat thick and so required a considerable time to become heated to redness and then in which to cool it was found necessary to have four in use, in series, and to employ a simple automatic apparatus, with the help of which they could be sterilised and cooled, each in turn. This apparatus consists of a double wheel and a delivery frame (see Fig. 1). On the circumference of the wheels are cut pairs of oblique notches in which the handles of the spoons may rest while the platinum cup is being heated in the flame of a Bunsen burner standing at the side of the wheel; there are six pairs of the notches, and three of them will hold spoons in whatever position the wheel rests. As each spoon after use is placed in position in a pair of these notches and brought into the flame the wheel revolves, moving the spoon previously in the flame into a position where it can cool; another spoon is moved still further from the flame,

time a spoon is introduced, so that, automatically, every time one is put into the flame another is delivered, sterilised and cooled. The use of this apparatus has resulted in a great saving of time and has enabled us to work with numbers of dilutions that without it could not have been

attempted. The secondary culture tubes .-For these, McConkey's bile salts medium was used. This medium encourages the growth of bacillus coli communis at the expense of other organisms. As the glucose is fermented the acid formed turns the blue litmus red and gas escapes as visible bubbles. It is pre-pared according to the following formula: sodium taurocholate, 5 grammes; glucose,

5 grammes; peptone, 20 grammes; Merck's litmus puriss (5 per cent.), 100 cubic centi-metres; distilled water to a litre. Ten cubic centimetres of this was placed in each test

٥

Fig. 1.

Apparatus for the sterilisation and cooling of a series of platinum cups. (This apparatus, together with the special inoculating spoons, may be obtained from Messrs. Baird and Tatlock of Cross-street, Hatton-garden, E.C.)

tube and the test tubes were arranged in racks; each rack contained the set of tubes to be inoculated after one of the time periods and each tube was labelled with a letter corresponding to the pot of disinfectant from which it was to be inoculated and a figure for the time during which the bacilli therein would have been under the influence of the disinfectant.

Preliminary tests.—Preliminary tests of the unknown disinfectant were first performed with dilutions at wide intervals in order to find out with what strengths a complete critical curve could probably be obtained—that is to say, one which was composed of the results obtained with at least one dilution which was strong enough to kill the bacillus coli communis in two and a half minutes and with one, at least, which was not strong enough to kill after 30 minutes. These preliminary tests were only done at the two and a half and five minutes' intervals and at 25 and 30 minutes, as from these sufficient data for our purpose could be obtained.

The method of conducting the experiments.—The series of dilutions of the unknown disinfectant were first tested, and then, immediately, the series of carbolic controls, or Very often a double series was carried out: vice versa. first one disinfectant, then the carbolic control series, and then another disinfectant, one after the other. After the various dilutions had been made up 5 cubic centimetres of

each were placed in order in a labelled specimen pot. The emulsion was now prepared and placed ready to hand, as were also the racks containing the tubes of secondary culture medium, and the sterilising apparatus on which the spoons were arranged. A stop-watch was started, and one after the other the pots of disinfectant were "seeded" with spoonfuls of emulsion, beginning at the strongest and finishing with the weakest; each seeding took altogether from 10 to 12 seconds, so that if there were as many as 12 to be "seeded" the whole process would occupy nearly the whole of the time available (2½ minutes). In taking out the seeding material the spoon should always be withdrawn from the fluid at the same speed, somewhat quickly. Unless this point is carefully attended to unequal, and often too small, quantities of the seeding material will be held in the spoon. A few trial samples should be taken and carefully measured or weighed until the experimenter is satisfied that at the speed at which he has to work he can take equal samples regularly and consistently. At the end of $2\frac{1}{2}$ minutes samples were taken from each pot in turn, again beginning at the strongest, and placed in the secondary culture tubes lettered to correspond; thus each pot was sampled after 2½ minutes; as a matter of experience the timing went very regularly after a little practice. The same process was repeated after 5 minutes, after $7\frac{1}{2}$ minutes, 10 minutes, $12\frac{1}{2}$ minutes, 15 minutes, 20 minutes, 25 minutes, and 30

Immediately after the unknown disinfectant series had been worked through the carbolic control series was begun. The pots were filled in the same way with the dilutions which experience showed were likely to give the required results: these dilutions lay between certain limits which had to be slightly modified in accordance with any rise or fall in the temperature of the room but it was not usually necessary to use more than seven or eight of these dilutions in the test. They were inoculated in the same fashion as were the disinfectant dilutions; at $2\frac{1}{2}$ minutes and at 5 minutes samples were taken from the stronger dilutions, and at 25 and 30 minutes from weaker dilutions; the beginning and end of a control curve were thus obtained.

It will be noticed on going over the tables that certain tubes were omitted; this was done simply on the ground of economy, as the result of the preliminary experiments showed us that these particular tubes would fall outside the line of the critical curve. In cases where tubes were omitted at the beginning of each time period an allowance, which would amount to about 12 seconds for each tube omitted, was made when taking samples; thus each tube was inoculated after its proper interval.

The temperature of the room.—This was always noted, and as it was found to seriously influence the result expressed as a coefficient (see results) all tests were done when the temperature was between 62° and 67° F. Tests that were carried out during a heat wave in August, when the room temperature rose to 72° F., showed a coefficient for two disinfectants 20 per cent. lower than at a temperature of 62° F., this being due to the great increase of germicidal activity acquired by the carbolic acid control as the result of a slight rise in temperature. For certain experiments carried out at a time when the temperature of the room fell below 62° F. a water bath with a standard temperature (64° F.) was used.

Incubation.—The tubes were collected in wire baskets and incubated at blood temperature for 48 hours. If regular observations were taken something like the following was found. After about 12-14 hours some of the tubes of media would be seen to be assuming a purple tinge which fairly rapidly turned to pink and in about two hours would be bright red and show by bubbles the formation of gas. This change, as might be expected, occurred first in the tubes in which the bacilli had been exposed to the power of the weaker dilutions of the disinfectant for the shortest periods.

During the next ten hours other tubes would show growth, and it was remarkable how regularly the curve showing positive results spread during this period in the direction of the stronger dilutions and the longer times. These time observations were, if possible, filled in on the result charts, and were of the greatest value as showing whether the experiment was proceeding satisfactorily and in conformity with other experiments. An example of this is seen in Table XIV., in which it will be noted that the numbers increase regularly from right to left and from above downwards. This delay in the appearance of growth after samples are treated by stronger dilutions for a longer time depends,

no doubt, on the fact that fewer bacteria, probably those that are more resistant, remain alive, and consequently require a longer time in which to multiply and to give evidence of their presence by the formation of sufficient acid to turn the medium red.

Tabulating the results.—On filling in a table with the results of the experiment—a plus sign (+) where growth had occurred and a naught (0) where the medium had remained sterile—if the experiment had been successful—a curve could be drawn by joining together the 0 signs indicating the points at which lethal action of each dilution was complete. After the disinfectant dilutions had been allowed to act for 2½ minutes, only the strongest had killed all the bacteria; in 5 minutes perhaps one or two weaker dilutions of the disinfectant were effective, and so on until in half an hour all but the very weakest dilutions had killed the bacteria that were introduced. At the commencement of the curve, therefore, the "dilution" factor was of first importance, at the end, the "time" factor. The importance of these individual factors comes out still more markedly owing to the approximation of the dilutions, as they get weaker in a geometrical progression.

The carbolic acid coefficient.—When the two curves of disinfectant and carbolic acid control results were obtained the coefficient was deduced as follows. The figure representing the percentage strength of the weakest lethal dilution of the carbolic acid control was divided by the figure representing the percentage strength of the weakest lethal dilution of the disinfectant being tested. This was done both at the 2½ minutes' line and at the 30 minutes' line and a mean of the resulting figures was taken as the carbolic acid coefficient.

PART III.—RESULTS OF EXPERIMENTS.

CARBOLIC ACID.

(1) Absolute Phenol.

After practice had led us to obtain and expect consistent results in the experiments carried out by this modified method, we decided that it was first essential to test pure carbolic acid thoroughly, using as many dilutions as convenient in order to obtain a definite idea as to what strength should be used in the control tests. The results of these experiments are given in the following tables, which represent two tests performed in sequence with the same dilutions, culture of organisms, &c.:—

4/6 09. Room temperature, 61° F.; + signifies growth; 0 signifies no growth.

Oertain points are brought out very clearly in these tables: firstly, the two tables resemble each other closely both in the position and form of the curve forming the "line of demarcation," secondly, irregularities and "misplaced" signs are practically absent. At each time-period there is a definite point on one side of which the dilutions have all been strong enough to kill, whilst on the other they have been too weak to do so. Similarly, for each dilution, the results show definitely at what time-period all the bacteria are dead. An exception will be noted to this last statement in the second series where a sample from the 0.786 per cent. mixture shows no growth at the 12½ minutes period, yet does so at 15 minutes; this is, of course, an imperfection, but only such as may be expected in a biological test, and the coefficient being determined in the way described above the results are not affected.

From these tables it is possible to work out a coefficient of carbolic acid against itself which should, of course, be unity.

The coefficient =
$$\frac{\left(\frac{1 \cdot 1}{1 \cdot 1} + \frac{0 \cdot 733}{0 \cdot 786}\right)}{2} = \frac{1 \cdot 00 + 0 \cdot 932}{2} = 0.966.$$

The error is therefore 0.034, and this may be taken as likely to occur in all our experiments, but the results are sufficiently exact for practical purposes. At a room temperature of 61° F. the dilutions 1·1 per cent., 1·0 per cent., 0·917 per cent., and 0·846 per cent. were sufficient, therefore, to give the demarcation point at the 2½-minute period and 0·786 per cent., 0·733 per cent., 0·687 per cent. and 0·647 per cent. for the 30-minute period. These dilutions, therefore, were generally used in the control tests, but as the weather became warmer and the temperature of the fluids used increased, it was found necessary to employ in addition weaker or stronger dilutions in order to include the points necessary for obtaining a coefficient.

Wishing to find out how the bactericidal power of the carbolic acid control would be affected by keeping, we performed a similar test with the same dilutions of phenol, after they had been kept, corked and in the dark, for 24 hours; this test also made in duplicate gave the following result :-

TABLE IV .- Absolute Phenol (Kept Diluted 24 Hours).

Minutes.	Percentage dilutions.												
minutes.	1.22	1-10	1.00	0.917	0.846	0.786	0.733	0.687	0.647

30	0	0	0	0	0	+	+	+	+				

5/6/09. Room temperature 62° F.; + signifies growth; 0 signifies no growth.

Here, again, we notice a close resemblance between the two tables: the curves indicating the line of demarcation are not without their imperfection (in the 0.786 per cent. dilution column in each instance), but as the coefficient works out at

$$\left(\frac{\frac{1 \cdot 10}{1 \cdot 10} + \frac{0 \cdot 786}{0 \cdot 846}}{2}\right) = \frac{1 \cdot 00 + 0 \cdot 929}{2} = 0.969 \text{ there is again}$$

only the same extremely low experimental error, 0.031. Apparently, also, the phenol loses very little of its bactericidal power if kept diluted only 24 hours, but we considered that this was sufficient to compel us to use freshly made dilutions for each experiment.

The influence of the temperature at which the disinfecting fluids are used can be studied by an examination of the 40 to 50 control tests carried out with carbolic acid; it will be seen that, roughly, the disinfecting power of the fluid increases as the temperature rises.

(2) Crude Carbolio Acid (Beall and Son, Chemists, Cambridge).

It was considered of interest to test this substance which, though at one time very cheap, has lately, owing to recent legislation, risen in price. A sample was purchased from a chemist.

Labelled—"CARBOLIC ACID (POISON)."
"For the disinfection of drains, cesspools, etc. and for the treatment of cattle diseases."
"To destroy all bad odours generated by the decay of Animal refuse, etc., etc. Mix one pound of the acid with ten gallons of soft water (warm if possible), stir well together and thoroughly rinse the pen, stable, or cowshed. Drains, stables, cesspools, etc., may be cleansed in the same manner.
With the view of impregnating the atmosphere of the pen, stable, etc., and of destroying all missma, place about the buildings, out of reach of the cattle, some of the undiluted acid mixed with a little sawdust or surface earth."

Physical characteristics. - A clear brownish fluid, which dissolves in water with some difficulty, and even after much shaking there are still some oily drops on the surface.

Chemical composition .- Per cent. : Phenols, 82.65; water, 2.80; inert bodies, neutral oils (by difference), 14.55—100.00.

Results of bacteriological tests.—The following table shows the results of a test :-

TABLE V .- Crude Carbolio Acid.

The coefficient is therefore-

$$\left(\frac{\frac{1\cdot00}{0\cdot250} + \frac{0\cdot733}{0\cdot166}}{2}\right) = \frac{4\cdot0 + 4\cdot4}{2} = 4\cdot2$$

(3) Calvert's No. 5 Carbolic Acid.

Labelled-"FOR DISINFECTING PURPOSES."

"This acid is highly concentrated and will arrest all kinds of putre-factive change and destroy ALL THE LOWER FORMS of insect or vegetable

life.

It must be WELL MIXED with warm water, in proportion of one ounce Acid to two quarts of water. The solution thus made is of sufficient strength to purify drains, water-closets, urinals, ash-pits, stables, cowsheds, etc., to cleanse rooms infested with insects, also to destroy weeds on garden walks, or bad odours and green moss in cellars or yards.

Half a pint of the SOLUTION added to any vessel used in the sick-room will prevent injurious effluvia or infection therefrom.

To prevent the spread of contagious diseases when prevalent, the floor should be DAILY sprinkled with the SOLUTION and ½ lb. well mixed with 10 lbs. of wet sand placed on plates in every room. A sheet should be hang over the door of the sick-room, and kept well saturated with the shove SOLUTION.

above Solution.

From dead bodies all infection will be prevented and all effluvia destroyed, by wrapping them in sheets asturated with the SOLUTION."

"N.B.—This acid is guaranteed (by Trade Mark on Capsule and Label) to be full strength and free from Tar Olls that are always in so-called Crude Carbolic acids which are not reliable disinfectants."

Physical characteristics.—An oily brown fluid insoluble in cold water except in weak dilutions, when it forms a clear solution.

Chemical composition.—Per cent.: Phenols, 93.26; water, 6.00; neutral oils, by difference, 0.74—100.00.

Results of bacteriological tests.—The following table shows the results of a test :-

TABLE VI.—Calvert's No. 5 Carbolic Acid.

30/9/09. Room temperature, 64°F.; the figures signify growth; 0 signifies no growth; ... signifies not tested. The figures also indicate roughly the number of hours that clapsed between the inoculation of, and the appearance of growth in, the tubes of McConkey's medium.

The coefficient is therefore-

$$\left(\frac{\frac{1\cdot 10}{0\cdot 400} + \frac{0\cdot 786}{0\cdot 333}}{2}\right) = \frac{2\cdot 7 + 2\cdot 4}{2} = 2\cdot 5.$$

KRYSYL. (Drum Sample.)

Labelled-"A NEW PHENOL DISINFECTANT.

Offers many advantages over carbolic acid.

Krysyl is non-caustic and is perfectly soluble with water, forming a milky, opalescent, non-separable mixture, whereas carbolic acid sinks to the bottom and consequently exerts but little effect.

Krysyl is regularly supplied to some of the largest municipal corpora-tions in the world as well as various Foreign Governments, and will be found one of the best and cheapest disinfectants and germicides on the

Krysyl will be found invaluable in warding off attacks of infectious disease such as small-pox and scarlet fever, and the daily use of an

efficient disinfectant in the house is certainly sonducive to the general

DIRECTIONS.—One part to from 50 to 100 parts of water, well stirred or, say, one wineglassful of Krysyl to a quart of water will form a disinfectant fluid suitable for use in closets, lavatories, sinks, drains,

Physical appearance.—A dark-brown, thick fluid, forming in solution with water, a milky emulsion.

Chemical composition.—Per cent: Phenols, 14·16; resins, fatty acids, &c., 15·22; water, 12·00; soda, 2·20; neutral oils, 56·42—100·00.

Results of bacteriological tests. - The weakest lethal dilution after $2\frac{1}{2}$ minutes' action was 1-100 (1 per cent.) in one experiment; 1-125 (0.8 per cent.) in two experiments; 1-150 (0.666 per cent.) in one experiment. The weakest lethal dilution after 30 minutes action was 1-175 (0.571 per cent.) in one experiment; 1-200 (0.5 per cent.) in one experiment; and 1-225 (0.444 per cent.) in one experiment. The following table shows the result of a test:-

TABLE VII. - Krysyl.

20/8/09. Room temperature 67°F.; ... signifies not tested. The figures in the table show that growth has occurred and indicate how many hours elapsed between the inoculation of, and the appearance of growth in, the McConkey medium.

The coefficient is therefore—

$$\frac{1 \cdot 00}{\frac{0 \cdot 80}{2} + \frac{0 \cdot 687}{0 \cdot 444}} = \frac{1 \cdot 2 + 1 \cdot 5}{2} = 1 \cdot 3.$$

ZOTAL.

Labelled-"Burgoyne's miscible disinfecting fluid.

THE MOST POWERFUL MISCIBLE FLUID DISINFECTANT IN THE MARKET. For hospitals, ships, and all domestic purposes.

MISCIBLE IN WATER.

PLEASANT TO USE."

"Owing to the concentrated form of this fluid, it will be found cheaper to use than any other Disinfecting Fluid in the Market.

DIRECTIONS FOR USE.—The proportions we name below may be altered, according as the necessity may arise, to increase or decrease the strength of the Diluted Fluid.

of the infection. Wash the Floors and Woodwork with a one in one hundred solution, and sprinkle Passages and Corridors with a similar solution. Half fill a few saucers with Zotal and place them about the rooms. Infectious cases may be more completely isolated by hanging a blanket saturated with Zotal outside the door."

Physical characters.—A thick dark-brown fluid, making in solution with 1-100 distilled water a primrose-yellow emulsion

Chemical composition.—Per cent.: Phenols, 10.00; resins fatty acids, &c., 35 42; water, 21 60; soda, 2 49; neutral oils, 30 49—100 00.

Results of bacteriological tests.—The table shows some imperfect results in the 1-175 (0.571 per cent.) column; these, however, do not affect the coefficient.

TABLE VIII. - Zotal.

29/8/09. Room temperature 64° F.; ... signifies not tested. The figures in the table show that growth has occurred and indicate the number of hours that elapsed between the inoculation of, and the appearance of growth in, the McConkey medium.

The coefficient is therefore-

$$\frac{1 \cdot 10}{1 \cdot 00} + \frac{0 \cdot 846}{0 \cdot 444} = \frac{1 \cdot 1 + 1 \cdot 9}{2} = 1 \cdot 5.$$

COOK'S "COFECTANT" FLUID.

Labelled-" THE DESINFECTANT OF HIGH AND REGULAR GUARANTEED

OBEFICIENT.

(Rideal-Walker method against B. typhosus.)

A Powerful Germicide and Deodorant.

Non-toric and Absolutely Safe for General Use."

"FOR GENERAL DOMESTIC PURPOSES: 'Cofectant' being a highly concentrated fluid, will admit of being diluted to any degree in warm or order after."

cold water.

DIRECTIONS FOR IUSE.—For general purposes 1 tablespoonful to an ordinary bucket of water; for drains, sinks, cesspools, 2 tablespoonfuls."

Physical characters.-A thick, dark fluid, making in dilution (1-500) with water a brownish-white emulsion.

Chemical composition. —Per cent. : Phenols, 66.27; resins, fatty acids, &c., 24.66; water, 6.40; potash, 2.67; neutral oils. 0.00-100.00.

Results of bacteriological tests.—All these came out very close together. The weakest lethal dilution at 24 minutes was 1-600 (0·166 per cent.) in two experiments; and 1-700 (0.143 per cent.) in two experiments. The weakest lethal dilution at 30 minutes was 1-1200 (0.083 per cent.) in one experiment; and 1-1300 (0.077 per cent.) in three experiments. The following table shows the result of a test with chis disinfectant.

TABLE IX .- Cofectant.

						Dilui	ions.

18/9/09. Room temperature, 64°F.; + signifies growth; 0 signifies no growth; ... signifies not tested. Taking into consideration the whole "line of demarcation," it is obvious that the misplaced positive result in the 1-800 (0:125 per cent.) column is a contamination; it does not after the confident. affect the coefficient

The coefficient is therefore -

$$\frac{1 \cdot 10}{0 \cdot 143} + \frac{0 \cdot 917}{0 \cdot 077} = \frac{7 \cdot 7 + 11 \cdot 9}{2} = 9 \cdot 8.$$

JEYES' FLUIDS .- A. Cyllin (bulk sample). B. Cyllin (Medical). C. Joyes' Fluid I. (sold by Chemists). D. Jeyes' Fluid No. 2 (sold by Grocers).

(A) Cyllin.—A sample from a half-gallon tin was tested.

Labelled-"JEYES' SPECIAL FLUID CYLLIN DISINFECTANT. GUARANTEED RIDEAL-WALKER CO-EFFICIENT 17."

"CYLLIN is supplied in concentrated form, and, for general use must be diluted with water (see directions for use). Its germleidal value has been proved by exhaustive experiments on vigorous cultures of the plague organism to be 30 times that of Carbolic Acid (pure Phenol) and over 80 times that of Formalin (40 per cent. Formic Aldehyde). See Public Health, June, 1904.

Public Health, June, 1904.

All the strengths recommended in the directions for use of CYLLIN allow for the further dilution with inert matter which takes place when the disinfectant is applied. At a strength of 1-400 even the highly resistant organism of pus (staphylococcus p. aureus) has been found by an eminent bacteriologist to be destroyed in five minutes (see British Medical Journal, 10 January, 1903, and LANCET, 21 March, 1903). Professor Fraenkel, in comparing CYLLIN with three of the leading disinfectants on the Continent, reports "we are justified in saying that CYLLIN takes the most prominent place, owing to its bactericidal properties, amongst all the substances here tested, and in all probability amongst all substances of the organic serier"; and further valuable testinony as to the bactericidal value of CYLLIN is supplied by Dr. Sommerville, whose recent experiments on the typhoid organism (B. typhosus) prove CYLLIN to be seventeen times more efficient as a true disinfectant than pure Carbolic Acid.

CYLLIN does not contain Carbolic Acid or any of its homologues, and is

CYLLIN does not contain Carbolic Acid or any of its homologues, and is free from the poisonous and irritant action of these agents.

Cyllin should be tested bacteriologically. Chemical analysis is not reliable means of ascertaining its value.

In consequence of the presence of Lime in varying proportions in ordinary tap-water, clean, soft-water should, if procurable, be used for dilution.

Directions for use:

FOR GENERAL HYGIENIO PURPOSES. Cesspools, Sinks, Lavatories and Urinals mix with water 2 teaspoonfuls to 1 quart," &c., &c. "Spittoons 1 temspoonful to 1 pint."

" FOR INFECTIOUS DISEASES.

Utensils and Floors, spray for walfs, i teaspoonful to 1 quart. Bath for soiled sheets, I tablespoonful to I gallon," &c., &c.

Physical characters. —A dark thick fluid, making a whitish emulsion with water.

Chemical constitution.—Per cent.: Phenols, 40.41; resins and fatty acids, 31.23; water, 10.40; soda, 2.24; neutral oils, 15.72—100.00.

30'8'09. Room temperature, 63° F.; ... signifies not tested. The figures in the table show that growth occurred, and also indicate the number of hours that elapsed between the inoculation of, and the appearance of growth in, the McConkey medium.

The coefficient therefore is-

$$\frac{1 \cdot 10}{0 \cdot \overline{166}} + \frac{0 \cdot 786}{0 \cdot \overline{071}} = \frac{6 \cdot 6}{2} + \frac{11 \cdot 1}{2} = 8 \cdot 8.$$

(B) Cyllin (Medical).

Labelled-"CYLLIN FOR MEDICAL AND SURGICAL USE (MEDICAL). RIDEAL-WALKER COEFFICIENT, 200.

For general medical and surgical use a strength of 1 in 200 is recommended (one teaspoonful to a pint of water).

When required for use in contact with a delicate mucous membrane-as a douche, &c. -1 in 400 is to be preferred."

Physical characters.—A dark-brown thick fluid, making in dilution with distilled water a whitish emulsion.

Chemical composition.—Per cent.: Phenols, 32.08; resins and fatty acids, $35 \cdot 11$; water, $6 \cdot 40$; potash, $1 \cdot 48$; neutral oils (by difference), $24 \cdot 93 - 100 \cdot 00$.

Results of bacteriological tests.—We made use of this disinfectant to a large extent in our preliminary experiments, taking it as an example of a typical coal-tar disinfectant. The results obtained in numerous experiments were very close. After 2½ minutes action the weakest lethal dilution was 1-300 (0·333 per cent.) in two experiments; 1-400 (0·250 per cent.) in two experiments; 1-500 (0·200 per cent.) in three experiments; and 1-600 (0·166 per cent.) in three experiments. At 30 minutes the weakest lethal dilution was 1-1100 (0.091 per cent.) in seven experiments; and 1-1000 (0.100 per cent.) in three experiments. These experiments were done under varying conditions of room temperature, age of growth, &c. In many cases phenol control experiments were not carried out as we wished in these cases simply to obtain the curve of the antiseptic itself. The following table shows the result of a typical experiment with this antiseptic.

TABLE XI. - Cyllin (Medical).

	Dilutions												
Minutes.	1-400	1-500	1-600	1-700	1-800	1-900	1-1000	1-1100	1-1200	1-1300	1-1400

5/7/09. Room temperature, 67° F.; ... signifies not tested. The figures in the table show that growth occurred and indicate the number of hours that elapsed between the inoculation of, and the appearance of growth in, the McConkey medium.

The coefficient therefore is-

$$\frac{1 \cdot 00}{0 \cdot 166} + \frac{0 \cdot 687}{0 \cdot 100} = \frac{6 \cdot 0 + 6 \cdot 8}{2} = 6 \cdot 4.$$

(O) Jeyes' Fluid (Chemists-Black label).

Labelled-" JEYES' FLUID DISINFECTANT."

It does not poison, burn, or stain.

"JEYFS' FLUID is far more efficacious than Carbolic Acid and is Non-poisonous."

"Certified by highest Scientific Authorities to be 'a true Germicide, a true Disinfectant and a true Antiseptic.

NOTE.—To comply with the order in Council f July 31st, 1900, this preparation is labelled POISON. The compound is as manufactured for over 20 years and is absolutely safe and FREE FROM CARBOLIC ACID." " Directions for use:

For general hystenic purposes: Drains, Closets, Urinals, mix with water, 1 teaspoonful to ½ pint. Shops, factories, schools, 1 teaspoonful to 1 pint, &c., &c.

For injectious diseases: Utensils and floor, 1 teaspoonful to 1 pint,

(D) Jeyes' Fluid No. 2 (Grocers-Brown label).

This has the same label and directions as Jeyes' Fluid (Black label) except that it is printed in brown, and instead of the note with regard to the Poisons Act has printed on it: "This Disinfectant is guaranteed exempt from the conditions of the Poisons Act." The dilutions recommended are the same. It has exactly similar physical characters.

Chemical composition .- Jeyes' Fluid (Chemists-Black label). Per cent.: Phenols, 17.80; resin, fatty acids, &c., 20.19; sods, 1.60; water, 6.40; neutral oils, 54.01.
100.00. Jeyes' Fluid No. 2 (Grocers—Brown label). Per cent.: Phenols, 5·13; resin, fatty acids, &c., 23·21; soda, 1·38; water, 22·40; neutral oils, 47·88—100·00.

Physical characters.—Both fluids are dark brown, thick, syrups, which, with water, form whitish emulsions and resemble each other closely.

Results of bacteriological tests. - In the case of Jeyes' Fluid (Chemists) the weakest lethal dilutions, under varying conditions, were, after 2½ minutes 1-125 (0 800 per cent.) in two experiments; after 30 minutes 1-300 (0.333 per cent.) in one experiment. In the case of Jeyes' Fluid No. 2 (Grocers) the weakest lethal dilutions were after 24 minutes 1-50

per cent.) in two experiments; and after 30 minutes 1-100 (1 per cent.) in two experiments; 1-110 (0.909 per cent.) in one experiment; and 1-120 (0.833 per cent.) in one experiment. The following tables represent the tests carried out with these two disinfectants.

TABLE XII. - Jeyes' Fluid (Black label).

The Jeyes' fluids were tested against each other with an intervening phenol control:-

$$\begin{array}{l} \text{Jeyes' Fluid (Chemists)} \\ -\text{Black label) car-} \\ \text{bolic acid coefficient} \end{array} \} = \frac{ \frac{1 \cdot 10}{1 \cdot 00} + \frac{0 \cdot 786}{5 \cdot 333} }{2} = \frac{1 \cdot 1 + 2 \cdot 3}{2} = 1 \cdot 7$$

LAWES' FLUID.

Labelled-"THE TRUE DISINFECTANT. Used by H.M. Government. THE PERFECTION OF PURIFIERS."

"Directions for use: Mix 1 large teaspoonful of Fluid with 1 pint of water or quarter pint of Fluid with 3 gallons of water and use solution as follows. For household Cleansing purposes, flushing sinks, w.c.'s, drains, &c. For spraying or sprinkling about the rooms to purify the air."

"FOR DISINFECTING NIGHT STOOLS AND CESSPOOLS mix double strength."

Physical characters. - A dark brown fluid, forming with distilled water a greenish-grey opalescent liquid.

Chemical composition.—Per cent.: Phenols, $28\cdot 20$; resins and fatty acids, $25\cdot 73$; sods, $2\cdot 60$; water, $13\cdot 60$; neutral oils, $29\cdot 87-100\cdot 00$.

Results of bacteriological tests.—The weakest lethal dilution after 2½ minutes was 1-140 (0.714 per cent.) in one experiment; and 1-225 (0.444 per cent.) in two experiments. The weakest lethal dilution after 30 minutes was 1-280 (0.357 per cent.) in one experiment; and 1-350 (0.286 per cent.) in two experiments.

30/6/09. Room temperature, 63° F.; ... signifies not tested. The figures in the table show that growth has occurred and indicate how many hours elapsed between the inoculation of, and the appearance of growth in, the McConkey's medium. This chart is an excellent example of the confirmation obtained of the correctness of the "line of demarcation" by these figures, showing how long a time elapsed before growth was noticed. Note how regularly the figures increase in the columns from right to left and from above downwards.

The coefficient of this disinfectant is, therefore—

$$\frac{\frac{1 \cdot 00}{0.714} + \frac{0.687}{0.357}}{2} = \frac{1.4 + 1.9}{2} = 1.65.$$

A previous test gave a coefficient of 2.1 (estimated).

McDougall's M.O.H. Fluid.

Labelled—"McDougall's M.O.H. disinfecting fluid (soluble in water in all proportions): Guaranteed carbolic coefficient 17 when tested against B. typhosus by the Rideal-Walker method.

This fluid is the most powerful germicide and bactericide known and has a guaranteed minimum carbolic coefficient of 17 when tested by the Rideal-Walker method against active typhoid germs. It is therefore from 17 to 40 times as powerful as pure carbolic acid according to the disease organisms against which it is used and is invaluable for destroying germs of All infective diseases.

Specially recommended for hospitals, sanitary authorities, public institutions, municipalities, sick-rooms, &c.

This liquid is non-corrosive, guaranteed free from mercury, and will not injure clothes, blankets, sheets, &c.

Directions for use: The following proportions are suggested as being suitable for the various purposes indicated, but the fluid may be used either weaker or stronger, according to circumstances.

To mix: Simply pour cold water into the Fluid and stir well. A strong mitky solution will be obtained. Don't use boiling water.

For general disinfecting purposes, sprinkling or spraying walls and seors of schools, disinfecting clothes, utensils, &c., 1 part to 400 or 500 parts of water or I teaspoonful to 3 or 4 pints water.

For flushing drains, sewers, urinals, and all places where the solution will at once become further diluted-I part to 50 or 100 of water, or 4 teaspoonfuls to from I pint to 2 pints water.

The most powerful Germicipe known. Although such a powerful Germicide and Bactericide, this fluid has little or no effect on the hands in its diluted form, and has a relative toxicity coefficient of 13, that its 70 SAY, a solution of M.O.H. fluid doing the same disinfecting work would be 13 times less poisonous than carbolic acid."

Physical characters.—A dark brown fluid. making a pinkish-This fluid is the most powerful germicide and bactericide known and

Physical characters.—A dark brown fluid, making a pinkishwhite emulsion with distilled water.

Chemical constitution.—Per cent.: Phenols, 47.13; resins and fatty acids, 33.54; potash, 2.10; water, 5.6; neutral oils, 11 · 63-100 · 00.

Results of bacteriological tests.—The weakest lethal dilution after $2\frac{1}{2}$ minutes' action was 1-700 (0 143 per cent.) in two experiments; and 1-600 (0.166 per cent.) in another experiment. The weakest lethal dilution after 30 minutes action was 1-1200 (0.083 per cent.) in one experiment; and 1-1300 The following (0.077 per cent.) in another experiment. table shows the result of a test :-

Room temperature, 63° F.; ... signifies not tested. The figures in the table show that growth has occurred and also indicate the number of hours that elapsed between the inoculation of, and the appearance of growth in, the McConkey's medium.

The coefficient is therefore-

$$\frac{1.00}{0.143} + \frac{0.733}{0.083} = \frac{7.0 + 8.8}{2} = 7.9$$

IZAL.

Labelled—"Non-poisonous.

N.B.—For internal use a special 'Medical Izal' is supplied, with

directions, dose, &c.
An antiseptic of greater power than pure carbolic acid:
Officially adopted by His Majesty's Government.
Shake the bottle.

Shake the outle.

DIRECTIONS FOR USE: For disinfecting discharges and all contagious or infected matter:—Dilute one tablespoonful of Izal with ten pints of water; mix thoroughly with material to be disinfected.

Linen or clothes should be immersed in a mixture of Izal of above

strength.
In cold weather, if congealed, warm the bottle and SHAKE WELL

BEFORE USING."
"Mixes equally well in salt, brackish, and fresh water," &c., &c.

Physical characters.—A thick whitish emulsion; when diluted it forms a milky fluid.

Chemical composition. —Per cent.: Phenols, 41.35; water, $47 \cdot 14$; soda, $0 \cdot 10$; non-resinous emulsifiers (gelatin), $11 \cdot 41$; neutral oils, traces— $100 \cdot 00$.

Results of bacteriological tests.—The tests on izal presented difficulties which were not met with in testing other disinfectants; the results obtained were apparently more liable to be influenced by such factors as the temperature of the room and the time elapsing between the preparation of the dilutions and the carrying out of the experiment. For that reason it was necessary to test this disinfectant many times. During these tests a different sample was sent to us, which appeared to be stronger, and in tests of these two samples we found that the weakest lethal dilution after $2\frac{1}{2}$ minutes' action was: 1-500 (0.2 per cent.) in two experiments; 1-550 (0.182 per cent.) in one experiment; 1-600 (0.166 per cent.) in three experiments; 1-700 (0.143 per cent.) in four experiments; and 1.900 (0.111 per cent.) in one experiment. The weakest lethal dilutions after 30 minutes' action was: 1-700 (0.143 per cent.) in one experiment; 1-800 (0.125 per cent.) in two experiments; 1-1000 (0.100 per cent.) in three experiments; 1-1100 (0.091 per cent.) in three experiments; and 1-1200 (0.083 per cent.) in two experiments. The coefficients found in certain of these experiments were 5.8, 6.5, 6.7, and 8.4, the last one being found by using the dilutions immediately after they were made up; in the case of the others there might be an interval of half to one hour between the preparation of the dilutions and the beginning of the test. This marked variability was not met with in connexion with the testing of any other disinfectant. The following is a good average result:

TABLE XVI.-Izal.

	Dilutions.													
Minutes.	1-700	1-800	1-900	1–1000	1-1100	1-1200	1-1300	1-1400	1-1500	1-1600

KEROL.

Labelled—"The Perfect Non-Poisonous disinfectant.
This preparation is guaranteed to be from 10 to 35 times more active than carbolic acid according to the organism selected.
Kerol is strongly recommended for the disinfection of the organisms of Tuberculosis (Consumption), Typhoid, Diphtheria, Plague, and other infections diseases. or Tuberculosis (Consumption), Typnoid, Diphtheria, Plague, at infectious diseases.

Non-poisonous, Non-corrosive, Free from Carbolic acid.

Absolutely unsurpassed in germicidal efficiency.

Directions for Use.

For infectious diseases.

Night commodes... 1 teaspoonful to 1 pint." "Soiled linen 1 ,,
Spray for walls 1 ,, to 1 gall. to 1 quart. Floors and utensils 1 to 1 ,,

FOR GENERAL SANITARY PURPOSES.

Lavatories, urinals, sinks, &c. ... 1 teaspoonful to 1 pint. Schools, factories, shops, offices, &c. 1 tablespoonful to 1 gall."

Physical characters .- A thick brown fluid, making, in dilution with distilled water, a whitish emulsion.

Chemical composition.—Per cent: Phenols, 40.56; resins, fatty acids, &c., 19.14; soda, 1.41; water, 2.40; neutral oils, 36.49—100.00.

Results of bacteriological tests.—The weakest lethal dilution after 2½ minutes' action was 1-500 (0.200 per cent.) in five experiments; and 1-800 (0.125 per cent.) in one experiment. The weakest lethal dilution after 30 minutes' action was 1-1100 (0.091 per cent.) in one experiment; 1-1200 (0.083 per cent.) in one experiment; and 1-1300 (0.077 per cent.) in three experiments. Coefficients estimated from these figures came out exceedingly closely. The following table shows the result of a test:

TABLE XVIII. - Kerol.

The figures in the table show that growth occurred and indicate the number of hours that elapsed between the inoculation into, and the appearance of growth in, the tubes of the McConkey's medium.

The coefficient in this case is, therefore-

$$\frac{1 \cdot 10}{\frac{0 \cdot 20}{2} + \frac{0 \cdot 917}{0 \cdot 091}}{2} = \frac{5 \cdot 5}{2} + \frac{10 \cdot 0}{2} = 7 \cdot 7.$$

THE SANITAS PREPARATIONS. (A) Sanitas Okol. (B) Sanitas-Bactox. (C) Sanitas Disinfecting Fluid.

(A) Sanitas · Okol.

Labelled—"Sanitas-Orol disinfectant. Shake well and only use freshly made and thoroughly mixed dilutions.
Germicidal Coefficient 20-22 according to the Rideal-Walker method of standardisation. Sanitas-Orol is not intended for internal administration, but it is not poisonous when diluted in accordance with the printed instructions.

printed instructions.

Directions for use: For general Disinfecting Purposes and in cases of Scartet Fever, Diphtheria, Small-Pox, Typhoid, and all infectious diseases mix 1 part with 500 or 1000 parts of water and apply by spray (preferably): add a teaspoonful to a gallon of water for washing the hands, face, &c.; and for washing floors, clothes, &c., add a tablespoonful to every gallon of water required, &c., &c.

For use IN WATER-CLOSETS; pour two or three drops into the pan every time the closet is used."

Physical characters. - A thick coffee-coloured emulsion. When diluted (1-500) with distilled water it forms a muddybrown emulsion on which there is a slight oily scum and in which, after standing an hour or two, a sediment is noticed.

With hard water a precipitate forms and falls to the bottom.

Chemical composition. Per cent.: Phenols, 48.50; non-resinous emulsifier, 5 90; soda, 0.20; water, 38.5; neutral oils, 6.90 -100.00.

Results of bacteriological tests.—The weakest lethal dilution after 2½ minutes' action was 1-600 (0.166 per cent.) in one experiment; and 1-700 (0.143 per cent.) in another experiment. The weakest lethal dilution after 30 minutes' action was 1-1400 (0.071 per cent.) in one experiment; and

1-1500 (0.066 per cent.) in another experiment. The following table shows a test carried out with this disinfectant:-

(C) Sanitas Disinfeoting Fluid.

(C) Sanitas Disinfecting Fluid.

Labelled—"Sanitas Disinfecting Fluid.

Labelled—"Sanitas Disinfecting Fluid. The Standard disinfectant for Sickness and Household use.

This ideal preparation is colourless, fragrant, non-poisonous, and does not stain linen. Being absolutely non-poisonous, it is the only disinfectant which may with safety be administered internally. Its active principles are those which are naturally generated in Pine and Bucalyptus Forests and include Peroxide of Hydrogen, Thymol, and Soluble Camphor. Sanitas Fluid is not merely an effective Germicide, but it is also an oxidising agent, and consequently acts as an air purifier owing to the nascent oxygen which it gives off.

For general use in the house and sick Rooms: Mix with four parts of water, sprinkle about the uncarpeted floors, and spray into the atmosphere, &c., &c.

For use in water-closets: Invert the cork and pour a little of the Fluid into the pan every time the closets are used."

Physical characters.—A clear greenish fluid: in dilution

Physical characters. - A clear greenish fluid; in dilution with distilled water no change is observed.

Chemical composition.—200 c.c. oxygen in 100 c.c.; 2.8

thymol, camphor, &c.; 0.18 soda.

Results of bacteriological tests.—The strongest non-lethal dilution after acting $2\frac{1}{2}$ minutes was 1-2 (50 per cent.) in one experiment; and 1-4 (25 per cent.) in another experiment. The strongest non-lethal dilution after acting 30 minutes was 1-5 (20 per cent.) in one experiment; and 1-8 (12.5 per cent.) in another experiment. The following table shows the result of a test :-

30/6/09. Room temperature, 63° F.; ... signifies not tested. The figure in the table indicate that growth has occurred, and show the number of hours that elapsed between the inoculation of, and the appearance of growth in, the McConkey's medium.

This table of results is not a good one, as there are no negative tubes in the 30-minute series. However, an approximate result (which is all we thought necessary in this case) can be obtained by estimating the coefficient from the weakest non-lethal dilution thus :-

e weakest non-lethal dilution thus:
$$\frac{0.917}{50} + \frac{0.647}{20} = \frac{0.018 + 0.032}{2} = 0.025$$

Labelled—"ANTISEPTIC AND DISINFECTANT.
Water soluble in any proportion.
The constituency and pure quality of this preparation is warranted by permanent control and endorsement of the following members of Universities and Veterinary Colleges: Professor Dr. Schotellius, Freiburg; Professor Dr. Engler, Karlsruhe; Professor Arnold,

Hanover.

According to the Pharmacy Act this preparation must be labelled 'Peison,' but if used as directed, no possible harm can result.

Directions for use: Lysol may be dissolved in either hot or cold water. To obtain perfectly clear solutions, employ soft or distilled water. Hard water w'll, on account of its lime, &c., turn the solution turbid, which, however, has no effect on its efficacy.

For the treatment of wounds in man and beast 1 per cent.

For general disinfecting and cleansing purposes 1-5 per cent."

Physical characters.—A brown thick fluid which forms a

Physical characters.—A brown thick fluid which forms a clear pale yellow solution in distilled water; in hard water the solution is turbid. The solutions lather on shaking.

Chemical composition.—Per cent.: Phenols, 50.96; fatty acids, 28.12; potash, 2.52; water, 18.40; neutral oils, 0.00—100.00.

Results of bacteriological tests.—The weakest lethal dilution after 2½ minutes' action was found to be 1-120 (0.833 per cent.) in one experiment; and 1-140 (0.714 per cent.) in two experiments. The weakest lethal dilution after 30 minutes' action was 1-240 (0.416 per cent.) in three experiments. The results obtained with this disinfectant were extremely regular and consistent. The following is an example of a test:—

GENERAL DISINFECTANTS.

Certain other chemical disinfectants were tested by the same method, but in view of the fact that the conditions of the test are so far removed from those of natural disinfection, the results are in no way comparable with those obtained in the experiments with coal-tar disinfectants, and are merely of technical interest. We have not thought it necessary, therefore, to reproduce the charts of results.

1. Perchloride of mercury.—This germicide showed a very high coefficient due to the fact that albumin was not present in the media in which disinfection took place. Moreover, the bacteria were not washed after the action of the disinfectant and, as other observers have shown, the slight combination occurring between the albumin of the bacterial cell and the perchloride of mercury was able to prevent growth. The coefficient worked out as follows:-

At
$$2\frac{1}{2}$$
 minutes = 2000 (circa).
,, 30 ,, = 6000 (circa).
Mean = 4000

2. Chloride of lime.—A particularly pure sample was obtained and tested. The coefficient was as follows:—

At
$$2\frac{1}{2}$$
 minutes = 45
,, 30 ,, = 93
Mean = 69

3. Formalia (formaldehyde 40 %).—This disinfectant differed from all others that we tested in so far that the time elapsing between the inoculation of the sub-culture tubes and the appearance of growth in them was much prolonged. This confirms the work of other observers which tends to show that formaldehyde may be regarded more in the light of an "antiseptic" than of a "disinfectant." The carbolic acid coefficient is low :-

PART IV .- SUMMARY OF BACTERIOLOGICAL EXPERIMENTS.

The disinfectants which we have tested may be classified as follows:-

TABLE XXIV.

LIST OF COEFFICIENTS (PURE PHENOL).

	· 	1	Coefficients.

•	SANITAS DISINFECTING FLUID	0.018	0.032	0.025

For the purposes of classification we have divided the coaltar disinfectants into two groups—those forming an emulsion and those forming clear solutions when mixed with distilled The former class can clearly be divided into two quite distinct groups, one with high carbolic coefficients, the other with much lower coefficients. In the stronger group this coefficient is between 6.4 and 9.8, and in the weaker between 0.75 and 2.2.

We do not, of course, pretend to insist that the order in which we have arranged the disinfectants in these groups gives an exact indication of their relative germicidal value, even under the limited conditions of our test. Moreover, we have chemical evidence that there must be variations from time to time in the composition of different batches of certain brands of disinfectants, and therefore, naturally, of their germicidal activity. Far less, therefore, can we claim that such an order holds good under the varying and little understood conditions obtaining in practical disinfection.

Though every care has been taken to maintain all the con-

course, that whereas it is impossible to insist upon the correct arrangement of the individual members of the stronger group, those contained in the second or weaker group may probably be more justifiably arranged in our table in the relative order of their germicidal power.

It must be borne in mind that this order is in terms of an artificial set of conditions, but we believe that it may be regarded as giving a rough indication of the value of these disinfectants in destroying the germs of disease under the conditions of natural disinfection.

When we come to compare those disinfectants which form emulsions in dilution with those which form more or less clear fluids, we have to bear in mind that we are now confronted by a physico-chemical problem with which at present we are not prepared to deal. It will be seen that the coefficient figures of the latter group (Group B) lie about midway between those of the stronger and those of the weaker group of disinfectants which form an emulsion on dilution.

Though every care has been taken to maintain all the conditions as uniform as possible, it is clear that any slight variation of temperature, altered resistance of bacteria, or other interfering factors which cannot be eliminated from a biological experiment might be sufficient to alter the figure obtained for the numerator from the carbolic control, with the consequence that the resulting coefficient figure might be increased or diminished by a few units in the first place of decimals.

Owing, however, to the general correspondence of the results obtained in between 45 and 50 tests of carbolic acid, and the closeness of the coefficient figures arrived at when the same disinfectants have been tested several times (as has been the case with most of them), we are satisfied that there is a wide interval as regards the germicidal power between the disinfectants of the stronger group and those of the weaker.

We find, when we come to consider the disinfectants in the weaker group, that the proportionate differences between them are certainly much greater than is the case in the stronger group. Indeed, it may be stated, very generally of

[The pressure put upon our columns this week by the publication (with tables) of the bacteriological results compels us to reserve for next week a further article dealing with the deductions of both chemical and bacteriological experiment besides certain important practical considerations.]

SOME CONSIDERATIONS OF MEDICAL EDUCATION.

IV.1

The Royal Colleges and the Preliminary Scientific Education of the Student.—Compulsory Registration of the Medical Student.

THE feeling left on the minds of those interested in medical education by the important proceedings at the General Medical Council in reference to the position of the English Royal Colleges and the preliminary scientific studies must have been a mixed one. Every member of the Council seemed to be agreed that there was hardly time for the medical student to do what was expected of him in five years, yet the claim of the Colleges to cut this period, apparently all too short, down to four and a half years was made with much force and backed by sound arguments. The weak spot in those arguments was that although the official curriculum might—at any rate, in theory—be shortened by six months, the amount of time actually spent in the preliminary subjects became unlimited. Subject to a boy being able to scrape together enough general knowledge to pass at some time or another a preliminary examination in arts, he might, if he liked, commence the study of chemistry, physics, and biology at 14 or 15. The difference of opinion between the Council and the Colleges raised several questions, such as the following: (1) Whether instruction given to schoolboys for an indefinite period of time, and while they are still carrying on their ordinary study of the humanities. is as efficient as studies forming part of a definite scientifie curriculum entered upon when general education is complete; (2) whether the Council ought to allow any corporations to admit students to their professional examinations who have received such instruction, even though the character of the instruction appears in some instances to be better than would be obtainable at certain of the medical schools; and (3) whether, as the action of the corporations might lead to an actual shortening of the curriculum for some students, the possibilities of such shortening of the curriculum ought not to be obvizted by the compulsory registration of the medical student in such a way that, however adequate his preliminary scientific instruction, no course should count as part of the statutory time of five years unless commenced upon or after the day of registration.

At the same meeting of the Council Sir John Batty Tuke made the third of these questions the most important one by introducing a motion founded on a Bill which he was prepared to introduce into the House of Commons for compulsory registration of medical students. The discussion of this motion was practically a continuation of the previous debate, inasmuch as compulsory registration of the medical student would naturally bring all the schools and institutions at which any training was received under the immediate jurisdiction of the General Medical Council.

Sir John Batty Tuke was able to say that the Bill would receive the support of the Privy Council. He used in favour of it the very forcible argument that the registration fees of the medical student of £1 per head would amount in the. aggregate to the useful sum of £1700 per annum, possibly £2000, and as at that date the finances of the General Medical Council were in a disadvantageous position any scheme by which the risk of a small annual deficit could be transformed into the certainty of an annual balance perforce commended itself to the Council. John Batty Tuke also argued that registration of the student would enable the General Medical Council to ensure that a course of study had been carried out for five years from a certain date by all students upon a plan that commended itself to the central authority. It would guarantee a proper preliminary examination and give the General Medical Council due discretionary power with regard to all places at which preliminary medical studies were carried out. In fact, it would enable the General Medical Council to occupy the position which it sought when desiring to have jurisdiction over the institutions sanctioned by the different corporations. He admitted that the Royal Colleges would lose the right of nomination of schools at which the arts and preliminary scientific studies would be pursued. Sir Victor Horsley seconded Sir John Batty Tuke's motion, holding it right that the autonomous interests of licensing bodies should be relegated to a secondary place in comparison with the general interests, public and professional, in a properly standardised scheme of medical education for the country. Dr. Norman Moore, representing the Royal College of Physicians of London, opposed the motion in uncompromising terms attributing to the Council a growing desire for money and power, which was felt to be a rather picturesque way of describing a situation whose real meaning was that the Council desired to live up to its ideals as the central authority in medical education and at the same time to pay its financial way. The admitted needs of the Council being introduced to Dr. Norman Moore's notice he said that his own solution for that difficulty was the non-payment of the members of the General Medical Council, a line along which argument was not pursued. Sir Henry Morris opposed the motion on behalf of the Royal College of Surgeons of England in a more convincing manner. It was perfectly clear that he was speaking in defence of the great corporation which he represented on the Council, but he took his stand rather upon the point that Membership of the Royal College of Surgeons of England had for many years been the qualification sought and prized by the mass of the medical profession in England. so that a protection of the privileges of the College meant the protection of the interests of the medical profession upon whose education the College had spent, and successfully spent, such an infinity of time and trouble. He characterised the attitude of his College as one of "defence not defiance." Dr. E. H. Bennett, the representative of the University of Dublin (Trinity College), took the same line in opposing the motion, but many other speakers, whether representing universities or colleges, or speaking on the particular issue or more generally, were found in Sir John Batty Tuke's camp. The present President of the Council, Sir Donald MacAlister, then representing the University of Cambridge, supported Sir John Batty Tuke's motion in a speech in which he described the General Medical Council as the only existing "inter-university board in the kingdom," and he thought that constitutional power should be given to the Council to maintain a plan of students' registration. Sir William Turner, at that time President of the Council and the representative of the University of Edinburgh, regretted the tendency of the Colleges to flaunt their charters in the face of the Council. His own University, he said, had undertaken not to allow unregistered

 $^{^1}$ Nos. I., II., and III. were published in The Lancer of Oct. 23rd (p. 1232) and 30th (p. 1301), and Nov. 13th (p. 1459), 1909, respectively.

students to proceed to qualification, and his strong support of the motion had undoubtedly much to do with the fact that it found favour with the meeting by 22 votes against 6 dissentients.

The compulsory registration of the student was not, however, destined to take place, as most of our readers know. Representations having been made to the Privy Council in an adverse sense by the University of Oxford and by the English Royal Colleges the Privy Council suggested that the General Medical Council should refer the matter to those bodies for further consideration. Sir Victor Horsley, at the next session of the Council, protested against such a course being taken, as it placed the Council in a false position, and ignored the fact that the Council was in itself by its very constitution a conference of the licensing bodies. Sir John Moore then brought forward a motion that the Council should request their views upon the subject from all the licensing bodies and should inform the Privy Council that this had been done. To this motion Dr. J. Y. Mackay proposed the following amendment :-

(1) That the Lord President of the Privy Council be informed that in the opinion of the Medical Council it would not be expedient at the present stage to confer with the Royal Colleges on the subject of the resolution of May 30th, 1904.

(2) That before proceeding further in the matter a memorandum be prepared setting forth the grounds on which the Council is acting in reference to the resolution, and giving the specific proposals which the Council thinks should be embodied in the contemplated Bill.

The amendment being carried the chances of registration again looked rosy. As the Council had come very deliberately to the conclusion that registration of the medical students was a properly progressive move, and as registration would place increased powers in the hands of the Council, it was right that the medical profession should know exactly what were the conditions, for example, as to standardisation, duration, and locale of preliminary study which the Council would recommend. But Dr. Mackay's amendment, when put forward as a substantive motion, was defeated by the following amendment proposed by Sir Christopher Nixon:—

That a reply be sent to the Privy Council, stating that this Council now sees great difficulties from opposition by certain licensing bodies in asking the Lord President to introduce a Bill giving to the General Medical Council statutory power to establish and maintain registers of medical and dental students, and to impose a fee not exceeding £1 for registration therein. The General Medical Council will be prepared at the proper time to offer an alternative proposition which it hopes may be approved of by the Lord President.

The Council, it will be seen, thus definitely withdrew all intention of asking the Privy Council to introduce a Bill giving to the General Medical Council statutory powers of registration over students. In fact, the Council came to the conclusion that the compulsory registration of students was impossible. It would require an Act of Parliament, and as the acquisition of powers under such an Act would be strenuously opposed by the Royal Colleges no such legislation would ever find a place on the statute book. The last part of Sir Christopher Nixon's successful amendment contemplated an increased registration fee to qualified medical men, a tax which would not be received with any gratitude by the medical profession. This proposition to raise the registration fees of practitioners took the debate frankly over to the fiscal side. The original idea was to standardise the medical education of the country throughout the kingdom and incidentally to raise money. The proposal to tax medical practitioners more highly left the question of medical education out entirely. The question of the compulsory registration of the medical student, however, is practically at an end. It is true that the suggestion has since been made that medical students should pay a registration fee of 5s., but as such a fee would be voluntary and as the collection of it would cause a disproportionate amount of trouble the proposal came to nothing.

(To be continued.)

THE MOTOR EXHIBITION AT OLYMPIA.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

II.

In addition to the exhibits described in THE LANCET of last week the following short digest of a few further perambulations at Olympia may prove of interest.

The Arrol-Johnston Co. have an attraction on Stand 51 in the car which was used in the Shackleton Expedition to the South Pole. Their 15 h.p. car makes its first public appearance at this show, and is in every way up to date—engine, flywheel, clutch, and gearbox all mounted as a single unit, accelerator pedal between clutch and brake pedals, high-tension magneto and coil and accumulator ignitions, gear-driven pump lubrication, with an easily detached oil filter. Four brakes are fitted, one inside of each wheel, those on the front wheel being made under the Allen-Liversidge patent.

The Austrian Daimler Motor Co., Limited, show on Stand 1 a 20-30 and a 15 h.p. petrol car, as well as one of their "Cedes" electric broughams. In the electric vehicle the motors are inside the rear wheels, thus eliminating a very considerable wastage of current, and being fixed solid within the wheels the motors take the place of the hubs and revolve round the central magnets, thus giving an increase of power for a comparatively low consumption of current. They are capable of travelling 20 miles an hour, and can do about 50 miles on one charge.

On the stand of Messrs. Crossley Brothers, No. 108, the Cowey Engineering Company show a pneumatic suspension which does away with the use of ordinary springs, substituting therefor a set of four cylinders filled with air at pressure and attached to the frame, while the piston rods are coupled to the axles. By an arrangement as the load increases extra air enters the cylinders, rolling when turning a corner being overcome by specially mounted transverse radius rods. If this invention answers solid tyres may again become fashionable and possible.

Enfield Autocars are on Stand 86. The new features of the 10-12 h.p. model are the adoption of thermo-syphon circulation and magneto ignition. One of these shown is fitted with a "racy" two-seated body, smartly finished in French grey. The 18-22 h.p. has now a channel underframe instead of the tubular pattern, and the back axle has an inspection door. Among other noticeable features are a new type of carburettor and improved foot-brake and steering connexions. In the Enfield "16" an entirely new model is introduced, which should certainly claim attention. It is a four-cylinder, with a bore of 86 mm. and a stroke of 108 mm., and has four speeds, gate-change, and magneto ignition.

The Lanchester Motor Co., Limited, are on Stand 72. Their cars in the early days can scarcely be said to have acquired a reputation for simplicity, though they were always known for quality. Those now shown, which include a 20 h.p. double landaulette and a phaeton of like power, prove that simplicity is undoubtedly now to be numbered among other Lanchester qualities. The starting handle, which was hitherto detachable, is now permanently attached to the front axle. Dual ignition is fitted. A feature which adds to comfort is a supplementary spring device built into the seat under the cushion.

The Talbot Stand, 52, like last year, is conspicuous for its display of handsome trophies -testimonies to the successes achieved by these cars at hill-climbs and other contests. From what I hear from happy owners they give satisfaction, and I trust shortly to be able to make a more intimate acquaintance with them, and thus to be in the position of writing after a personal test. The car which the company advocate for doctors is their 12 h.p., with four cylinders cast in pairs, 80 mm. bore by 120 mm. stroke, lubrication by pump, with a large sump in crank-case carrying sufficient oil for 250 miles. Two independent ignitions are fitted, and there are four speeds working in a gate, with the usual bevel The little points seem to have been thought of, live axle. and the shackle pins are all case-hardened and fitted with lubricators. The body has the now popular high side doors to the driver's seat and there is (what so many drivers desire) a clear dash.

The Thames Ironworks Shipbuilding and Engineering Co., Limited, show on Stand 77 four types of "Thames" cars The 8 h.p. single-cylinder victoria has variable friction transmission. The 12 h.p. two-cylinder coupé is of the unit construction type, and the rear axle is driven by propeller shaft worm-gear. This car is suitable for a doctor's use, as the driving seat can be completely protected by closing the very roomy body. A landaulette is mounted on a similar chassis and is of the usual type, capable of being completely opened, and a folding canopy is arranged over the driver's seat, and can be folded away, if not needed, in a receptacle on the dashboard.

The Riley Cycle Co., Limited, have on Stand 146 six specimens of their 9 h.p., 10 h.p., and 12–18 h.p. cars. Their speciality is a two-cylinder engine having its cylinders set at 90 degrees, which is claimed to give a perfect balance of moving parts. Their detachable wheels are also shown.

Messrs. Rolls-Royce show on Stand 57 three examples of

Messrs. Rolls-Royce show on Stand 57 three examples of their six-cylinder 40-50 h.p. cars. The double-limousine is most luxuriously appointed, and contains every accessory for comfort. An interesting display is a number of parts of the chassis in the rough and finished state.

On Stand 95 Messrs. Martini, Limited, are exhibiting a 10-12 h.p. chassis, a 10-12 h.p. two-seater complete with hood, screen, lamps, &c., and a 13-16 h.p. chassis. All are fitted with four-cylinder engines, with the valves arranged diagonally in the cylinder head, and operated by a single cam shaft driven by skew gearing from a vertical spindle in front.

Lancia Cars, Stand 18, are of 20 h.p. and are built on the most modern lines, with the gearbox in close proximity to the engine. Two of the bodies by Messrs. John Maythorn are bound to attract attention on account of their fine appearance.

At one time there were on the road probably more Humber cars than any other make, and one of their most popular types was described in The Lancer of April 11th, 1908. On Stand 48 this firm have their 1910 stud, which is confined to three models—an 8 h.p. two-cylinder and a 12 and 16 h.p. four-cylinder.

On Stand 41 the Gladiator Company show three 12-14 h.p. cars. This car has been improved only in detail, the general construction remaining the same as in the 1909 type. Specially designed valve tappets are employed to eliminate noise. On the larger models a new type of carburettor is fitted. On one chassis a fine single landaulette by Thorn is mounted.

The British Motorloc Syndicate, Limited, are on Stand 142. They are the pioneers of the "unit system," and show four of their 14-16 h.p. cars. The special points are parallel engine suspension, thus enabling easy access to the big ends, and all the wheels are fixed by hexagons.

Messrs. Berliet Motors, Limited, have on Stand 135 one 12 h.p. and two 15 h.p. cars. They have forced-feed lubrication, multiple disc clutch, and thermo-syphon cooling. One of the 15's has a light phaeton body by Messrs. Max Graddon, detachable wheels, and a light aluminium windscreen, while another has a landaulette body by Alford and Alder.

Messrs. Bedford Motors, Limited, claim that they have the cheapest four-cylinder car on the market. It is 15-18 h.p., with planetary gearing, dual ignition, and cardan shaft drive. The valves are mounted on top of the cylinder castings and are operated by long push-rods and rocking levers.

Personally, I do not consider that the mushroom valve is a cause of much trouble. Still, those who are in search of a car without these parts can find one in addition to those shown by the Daimler and Minerva companies. Valveless cars are shown by a company of that name on Stand 93. The engine has two vertical cylinders side by side, joining in a common combustion chamber at the top. In one cylinder there is a slot which admits the charge, in the other cylinder another slot through which the exploded charge escapes. The pistons operate two crank shafts which revolve in opposite directions, and are geared together, so that the pistons move up and down in unison. An ordinary automatic carburettor is fitted. When the pistons ascend they compress an explosive charge, which is ignited by a single sparking plug in the ordinary way, the pistons are driven down, the exhaust slot is uncovered, and the exploded gases are thus got rid of. At the time the pistons compress a charge, a vacuum is created in the crank-case, which is airtight, but has a guarded passage leading to the outside

air, and as a result of this vacuum air is drawn into the crank-case, where it is carburetted, and, as the slot becomes uncovered, is passed into the cylinder head, compressed, and exploded. Thus the cycle of operations is repeated, one charge being compressed and exploded while the next is prepared in the base chamber. The first charge is supplied by turning the handle in the ordinary way. Every time the engine fires, the two connecting rods, crank shafts, and flywheels are accelerated in opposite directions, and as the pistons are balanced by weights on the crank shafts there is freedom from vibration and smooth running. This engine provides for an impulse to both pistons at every revolution, thus ensuring great engine flexibility. A cross shaft driven by one of the crank shafts drives the magneto and oil and water pumps. From the second flywheel the power is transmitted by an ordinary leather cone clutch to a gearbox, and thus on to a live axle. This car was subjected to a 1000 miles' trial under the Royal Automobile Club's observation, which was completed with only one stop of one minute to lubricate one of the universal joints. It certainly appears to be well designed, original, and yet free from complications.

In patrolling the main and side arteries of the Show the visitor will be impressed with the number of cars with small engines, mostly four cylinder, but some, like the 20 h.p. Standard, 16 h.p. La Buire, 30 h.p. Napier, and 15 h.p. Delaunay-Belleville, with six cylinders. Many of the small fours are wonderfully cheap and for the price marvellously good. Still these bargains (and I admit that some of them are certainly bargains) are not good for all with a slender purse. It is not merely the purchase price but also the upkeep that must be taken into consideration. These cheap four cylinders are very tempting. In fact, a purchaser who merely wants a car for his practice is apt to reason that a good single cylinder will cost complete not far short of £180 or £200; then why not give another £50 and have a four-seater four cylinder with all the latest improvements? Certainly it is alluring, only the general practitioner with a small income should also remember that the running cost, repairs, and tyres of the small two-seater is about half, if as much, as those of the cheap four cylinder. Probably some of the manufacturers have also thought of these points, for another feature in the Show is the reappearance of the "One Lung Car." The Rover, De Dion, Jackson, and Sizaire-Naudin people have always built these cars, and they continue to do so, and among others the Swift and Austin have now entered this field. So those who, anyway to begin with, want a single cylinder will find a fair number to choose from. The general tendency is to cast the small four cylinders en bloc with the valves all on one side. High-tension magneto seems the prevailing form of ignition, and is deservedly so, as being more simple and more reliable than the low tension with its make-and-break mechanism and the tappets. The Silent Knight type of so-called valveless machine has rather put the ordinary poppet valve manufacturer on his mettle, and hence the improvement in valve tappets and cams, as well as in some instances, as on the Napier, the complete encasement of not only the cam shaft, but also the valve and tappet guides. Certainly these improvements make for silence. On a few cars the overhead valve tappets are fitted, but this is the exception.

Partly, I presume, as a result of the 4-inch race, and also because of the new tax on horse-power, which will probably be estimated by the Royal Automobile Club's rulethat is, by the bore, irrespective of the stroke-long-stroke engines are the rule, as with the same bore a longer stroke gives a greater horse-power. But it must be remembered that this increase of stroke means longer and heavier crank shafts and connecting-roos, increase of thrust of the pistons on the sides of the cylinder, as well as increase in weight of clutch shaft and transmission gear. On the smaller engines thermosyphon cooling, with pipes of very large proportion, is the fashion, and this innovation certainly seems to have the merit of success. The lubricator boxes on the dash-board are vanishing, and in their place is a small indicator that shows if the pump lubricator in the crank case is working. The innovation has much in its favour, only care should be taken that the pump can be removed easily from the crank case in case it requires attention. The leather-faced cone clutch, I am glad to see, is not dead, though perhaps the multiple disc type has a few more adherents. Carburettors of a simple type are luckily still popular. In fact, on the new Darracq the mixture-making apparatus is simplicity itself, and the jet can be removed in a second without any dismantling. Multiple jets, however, claim more followers. The gate-change has, to the advantage of all, come to stay. To the maker it means shorter shafts in the gearbox, and to the owner greater ease in changing gears. In transmission the chain is vanishing, and now the Panhard are producing cardan shafts with live axles. A large number of cars, including some of the Napier, Wolseley, Thames, New Engine Co., as well as the Lanchester and Dennis, who always favoured this method, now have worm drive in place of bevel. Of course, in both types the thrust is an objection, but in a well-designed worm, where there is a big surface always in contact, and the movement is more sliding than rolling as in the bevel drive, the balance of favour is certainly with the worm.

The springing of the car has certainly improved, and the three-quarter elliptic is deservedly popular. As to bodies and coachpainting, the "Long Acre" part of the show is crowded with fine specimens of British and foreign work, and all will note with pleasure that the native builder compares favourably with the continental. High side doors and a curved overhanging dash are the rule, and will certainly add to comfort if the approaching winter is at all severe. I rather hoped to see more cars with front wheel brakes, but probably that will come in due course.

Most car owners now have pits, so as to be able to get underneath their automobile for periodical examination of the steering gear, axles, &c., and doubtless many a serious accident might have been averted if these "vitals" of a car were examined more often. Those who do not possess a pit will appreciate the auto-creeper—an appliance shown by Tom Norton, Limited, of Llandrindod Wells, which is justly called the chauffeur's friend and tailor's enemy. It is made of wood, runs on castors, and consists of a sort of tray on which the chauffeur can lie down comfortably, there being a pad for the head. Resting thus he can pull himself under the car, and make any adjustments or inspections. On the same stand (No. 184) are shown the Norton stoves, which are specially designed for heating private motor garages. Of course, in frosty weather glycerine can be added to the water in the radiators and cylinder jackets, or it can be emptied every night. The latter process is troublesome, as it is not easy to make sure that every drop of water is got rid of, and then, should a hurried call come, it is even more worry to fill up with water and to be certain that an air lock does not interfere with the water circulation. So on the whole warming of the garage is the easiest and safest procedure in frosty weather, and as the Norton stove is sanctioned by the leading fire insurance companies it is certainly worthy of inspection.

THE HEALTH OF THE NAVY.1

THE Statistical Report on the Health of the Navy for 1908, issued in September, shows a continuous improvement in the general health of the fleet, as compared with the preceding five years. It deals with a total force of 109,210, of whom a large majority—viz., 74,030—were serving in our own seas, in this point presenting a contrast with the military forces, about half of these constantly serving abroad.

The health returns are satisfactory, showing lower ratios of cases of sickness and injury, invaliding and mortality, also a slight diminution in the average loss of service for each man as compared with the previous quinquennial average. For the whole force the average sick-rate was 28.32 per 1000, showing the substantial decrease of 2.58 in comparison with the previous five years. The average loss of service was 10.36 days for each person, being 0.92 less than the previous average. The highest ratio of men sick daily occurred, as before, in what is called the Irregular List—that is, the crews of vessels on passage to or from foreign stations and of vessels on the west coast of America; it amounted to 48.02 per 1000. Next to this comes the Home Station, with a daily ratio of 34.72. On the China Station the ratio was 29.04 and in the

East Indies 28.68. All the other fleets had a lower figure than the average, the Channel Fleet having the lowest, 22.64. It is to be noted that this year what has been hitherto called the Home Station is divided into "Home Station" and "Home Fleet," the depôts and training ships being grouped under the former heading. This seems to be an improvement, as there is considerable difference between the circumstances of such service and the ordinary sea-going conditions.

The relative importance of the principal diseases that prevail in the Royal Navy is best seen by considering the ratios per 1000 of cases admitted and of daily sick. For all causes together 692 cases per 1000 of strength were treated, and 28 per 1000 were sick every day. The most important group of affections was that of venereal diseases, which accounted for 122 admissions and 8 daily sick per 1000 of strength; for digestive diseases the cases were 102 and the daily sick 3 per 1000; diseases of the connective tissue and skin and of the respiratory system, with 82 and 75 admissions per 1000 came next in importance.
The most prevalent single affection (except gonorrhosa) was influenza, for which there were 33 admissions per 1000; but it was not of a severe type, the daily number of sick from this cause being 0.77 per 1000. Local injuries, as might be expected, were frequent, causing 141 admissions per 1000, and 4.65 constantly sick. All of these ailments, however, have affected the service less in 1908 than in the preceding five years period, except influenza and venereal disease, in the former case the increase being probably fortuitous. It is regrettable that syphilis, chancroid, and gonorrheea are still so prevalent, showing little signs of diminution; primary syphilis and chancroid, indeed, have fallen from 34 to 27 admissions per 1000; but secondary syphilis has risen from 26 to 28, and generative from 61 to 67 cases per 1000, as compared with the five years 1903-07. most serious causes of death from disease were pneumonia (47 deaths, or 0.43 per 1000), and tuberculosis (37 deaths, or 0.33 per 1000). Enteric fever caused 20 deaths, or 0.18 per 1000 of strength. The chief causes of invaliding were tuberculosis (268 cases, 2.45 per 1000) and diseases of the digestive system (277 cases, 2.53 per 1000), affections of the teeth and hernia. On comparing the statistics of the different commands, it is seen that the East India Station suffered most; the case-rate was 1090, the constantly sick-rate 29, and the death-rate 7.55 per 1000, while the invaliding was as high as 45 per 1000; the number of men on the station was, however, only 1720. Of the 13 deaths that occurred, 2 were due to wounds in action and 2 to malaria. The healthiest commands were the Atlantic Fleet (601 cases of sickness and 2 deaths per. 1000), and that at the Cape (607 cases and 0.87 deaths per 1000); the Channel and Mediterranean Fleets were nearly as healthy with 616 and 610 cases per 1000, and 2.12 and 2.04 deaths per 1000 respectively.

Turning now to some of the most important diseases, we find that 3643 cases of influenza were admitted to treatment, 4 died and 1 case was invalided; it prevailed in all the commands, except in the East Indies, but was most rife in the Channel Fleet, the Home Station, and the Home Fleet. There were 75 cases of diphtheria, occurring not only at home, but also in the Atlantic Fleet, North America and West Indies, East Indies, and Australia; there were 3 deaths. There were 151 cases of enteric fever, with 20 deaths; the disease was present in every command, except that of the East Indies. Nine cases occurred on H.M.S. Vivid, but it is stated that they all contracted the disease while on leave (Home Station); 4 cases occurred on H.M.S. Donsgal and 6 on H.M.S. Leander (Home Fleet). H.M.S. Soylda had eight cases, five of which were contracted at Bermuda, and one (a medical officer) by apparent infection from a previous case. The other cases were all isolated ones. No general cause appears to have been in operation.

Only in two commands do fresh admissions appear as due to Malta fever. In the Mediterranean, with an average strength of 9780, there were 6 fresh admissions (0·61 per 1000); in the preceding five years the average annual admission-rate was 14·67 per 1000, while 0·34 died and 10·22 were invalided. The daily sick ratio is now 0·09 per 1000, or actually not quite one single sailor constantly in hospital on an average. No death occurred, and the invaliding was 0·3 per 1900, as compared with 10·22, the

Sens, Fetter-lane, E.C. Price 8d.

quinquennial average for 1903-07. From a strictly utilitarian point of view the improvement is best shown by the statement that during the year the "number of days lost" to the Service was 1000; five years ago (1903) it was 30,541. Malaria showed the comparatively high admission-rate of 7 per 1000, due principally to the East Indies Station, where there were 435 admissions, chiefly in Bombay, on board H.M.S. Perseus; the men lived in the Sailors Home, where they were supplied with mosquito nets, but worked on board ship every day; and it is noted that mosquitoes swarmed there and bit all day long. We cannot help wondering whether, if the anopheles was recognised (as it surely must have been), attempts were made to exterminate the pest; or failing that, to protect the men by the use of some culicide, or by giving quinine. This may have been done; but all that is said is that "the year had been an exceptionally severe one, as regards malaria, all over India. This is emphatically nil ad rem. Tuberculosis was accountable for 37 deaths and 268 invalidings, being still the most serious and fatal morbid condition in the Navy; the ratios per 1000 were 3.08 cases, 0.33 deaths, and 2.45 men invalided, each item, however, showing a slight improvement on the pre-ceding quinquennium. The Mediterranean Fleet and the Irregular List showed the greatest prevalence; but the numbers are not large enough to suggest any reason for this incidence, though in each case the average of the previous five years was exceeded. Pneumonia was the cause of more deaths (47), but only occasioned 7 invalidings. Rheumatic fever caused 6.5 admissions per 1000, and an invaliding ratio of 0.74; there were 712 cases in all, with only 1 death

It is worth noticing that in the whole Navy the cases of alcoholism numbered not more than 113-i.e., 1.03 per 1000; 2 deaths occurred and 2 men were invalided for this cause. A large number of cases of respiratory disease were admitted (74.56 per 1000), but they were mostly trivial, coming under the head of "catarrh." Under digestive Under digestive system there were 102 per 1000 admissions, with 2.53 invalidings and 0.23 deaths; tonsillitis and sore-throat accounted for a large proportion of the cases, and a large number (2723) are lumped together under the head of "diseases of the intestines "—a designation conveying, perhaps, an irreducible minimum of information. The invalidings for digestive disease, 2.53 per 1000, were more numerous than for any other class, but it is not possible to discover what were the causes, except that 24 cases of hernia were invalided after refusing operation. Local injuries caused 141 per 1000 admissions and 4.65 daily sick, leading to 1.21 invalidings and 0.13 deaths. General injuries were not more numerous than usual (2.14 cases as compared with the quinquennial average of 2.83 per 1000), but of the actual 234 casualties 115 were fatal, 98 being cases of drowning, 15 multiple injury and burns and scalds, 1 heat-stroke, and 1 disappearance of an officer on the West Coast of Africa. occurred in action off the Makraan coast of Baluchistan, while patrolling for arms-running dhows. Deaths by violence in all amounted to 1 · 19 per 1000, which, considering the enterprise and disregard of danger that characterise the British Navy, appears to be a very low figure. Of the 98 deaths by drowning 58 were due to the Gladiator and Tiger disasters.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on Nov. 11th, Mr. BUTLIN, the President, being in the chair.

The following resolution was carried:-

That the Council do hereby express their great regret at the death of Mr. Henry Hugh Clutton, who for the last seven years has been a member of the Council and taken an active part in the affairs of the College. While recording their sorrow at the loss of so useful a colleague the Council would take the opportunity of saying that Mr. Clutton will long be remembered by them with affection and esteem on account of his attractive disposition and his interest in all that concerned the welfare of the College. The Council also desire to express their deep sympathy with Mrs. Clutton and family in their anxiety during the long illness which has now terminated in his death.

It was resolved to issue diplomas of Membership to 99 successful candidates.

The SECRETARY reported that the by-laws relating to the admission of women and other matters have been signed by

the Secretary of State for Home Affairs, the Lord Chancellor, and the Lord Chief Justice.

It was resolved to adopt the form of the diplomas to begranted to women which had been recommended by the President and Vice-Presidents.

A letter was received from Sir T. Rudolf Smith, Bart., thanking the Council for their resolution of sympathy on the death of his father, the late Sir Thomas Smith.

The PRESIDENT reported that the Bradshaw lecture will be delivered by Mr. F. R. Cross on Friday, Dec. 10th, at 5 P.M., and that the subject of the lecture will be "The Brain Structures concerned in Vision and the Visual Field." The President stated that Mr. Bernard Pitts's period of office on the Court of Examiners will expire on Dec. 8th next, and that the vacancy thus occasioned will be filled up at the ordinary meeting of the Council on Dec. 9th.

The SECRETARY announced the notices of motion for the annual meeting of Fellows and Members on Nov. 18th.

Looking Back.

THE LANCET, SATURDAY, Nov. 19th, 1881.

(In this issue of THE LANCET no fewer than 44 pages are taken up with a History of the Rise, Progress, Ravages, &c., of the Blue Cholera in India, supplemented by a special map of the Progress of the Cholera. From this long account we can only cull the following excerpt.)

Even though the general immunity were confirmed, the force of the habitual exposure of medical men to insalubrious effluvia, and the consequent insusceptibility they must gradually acquire, should be taken into consideration. Moreover, of all men, physicians and medical attendants are accustomed to view disease with the greatest equanimity; and who is there who will doubt the efficacy of this counter-influence? Once for all, then, we have to repeat that even though the general immunity were fully proved, it would not disprove the contagious nature of cholera, it would only show that the individuals exposed were not susceptible of its effects. Let us, for example, view the malady in some other place than in an hospital. The medical attendants and the bystanders escape. Have they not been exposed to the same causes, whatever be their kind, as the patients they visited? Moreover, one of the main champions of anti-contagionism boldly declares that there is no latent period in the operation of the poison; in other and simpler words, that seizure is instantly consecutive on exposure. But suppose we cast all these facts overboard, and once more contemplate the phenomena of typhus fever, why, according to Mr. Searle and the other disclaimers* at the Egyptian Hall, every medical attendant who treated a case of fever should perish.

* "Mr. WHITLAW declared, that the disorder all over the world arose from eating bad RICE and RYE, which a destructive worm infected, and which carried off 20,000 people in New York !!!"

THE CHILDREN'S HOME HOSPITAL, ABERFOYLE.-This institution, of which the Duchess of Montrose is the honorary president, has for its main object the provision of open-air treatment combined with rest for children suffering from external or surgical tuberculosis. The work of the hospital is carried on in connexion with, and is supplementary to, that of the Glasgow hospitals. The sixth annual report, dated August, 1909, states that the total number of children received during the last 12 months was 55, and there remained in the home on July 31st, 1909, 23 patients. The total working expenses of the home for the year were £615 17s. 3d., and the statement of accounts shows a deficit of £101 16s. 4d. The report contains an appeal for a sum of £5000 for the purpose of building a new home outside the village of Aberfoyle. More open space is required for outdoor treatment where the patients would be less at the mercy of the dust from the main road, by the side of which the home is at present situated.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8097 births and 4353 deaths were registered during the week ending Nov. 13th. The annual rate of mortality in these towns, which had been equal to 12.0 and 13.3 per 1000 in the two pre-ceding weeks, further rose to 13.8 in the week under notice, and exceeded the rate recorded in any week since the middle of May. During the first six weeks of the current quarter the annual death-rate in these towns averaged 12.7 per 1000, and in London during the same period the rate did not exceed 12.5 per 1000. The lowest annual rates of mortality recorded in the 76 towns last week were 2.0 in Work Hartlands 5.0 in Buddies 5.0 in Work Hartlands 5.0 in Buddies 5.0 in Particular 5.0 in Work Hartlands 5.0 in Buddies 3.9 in West Hartlepool, 5.0 in Reading, 5.2 in East Ham, and 5.4 in York; the rates in the other towns ranged upwards, however, to 19.2 in Burton-on-Trent, 20.3 in Bootle, 23 · 1 in Stockport, and 24 · 2 in Hanley. In London the recorded death-rate last week rose to 13.9 per 1000. The 4353 deaths registered in the 76 towns last week showed a further increase of 173 upon the numbers returned in the two preceding weeks, and included 261 which were referred to the principal epidemic diseases, against numbers declining steadily in the 11 preceding weeks from 849 to 283; of these 261 deaths, 68 resulted from diarrhea, 48 from whooping-cough, 44 from scarlet fever, 41 from diphtheria, 40 from measles, and 20 from "fever" (principally enteric), but not one from small-pox. The 261 deaths from these epidemic diseases last week were equal to an annual rate of 0.8 per 1000, which was lower than the rate from these diseases in any previous week of this year. No death from any of these epidemic diseases was registered last week in Croydon, Tottenham, Norwich, Wolverhampton, or in 14 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2.2 in Preston, Bolton, and Smethwick, 2.7 in Newport (Mon.) 3.5 in Rhondda, and 6.1 in Hanley. The deaths attributed to diarrhea in the 76 towns, which had declined in the 11 preceding weeks from 675 to 110, further decreased to 68 last week; the highest death-rates from this cause last week were 1.3 in Devonport and 2.3 in Rhondda. The fatal cases of whooping-cough, which had been 42 and 31 in the two preceding weeks, rose to 48 last week; they caused annual rates equal to 1 · 1 in St. Helens and 1 · 3 in Plymouth. The 44 deaths from scarlet fever showed a further increase upon recent weekly numbers, and included 14 in London and its suburban districts, 7 in Manchester, 4 in Birmingham and Smethwick, and 3 in Liverpool. The 41 fatal cases of diphtheria showed a further slight decline from the numbers in recent weeks; 13 occurred in London and its suburban districts, 4 in Manchester and Salford, 3 in Birmingham and Smethwick, and 2 both in Bristol and Nottingham. The 40 deaths from measles showed a decline of 3 from the number in the previous week, but caused annual rates equal to 1.1 in Hornsey, 1.3 in Newport (Mon.), 1.4 in Ipswich, and 5.3 in Hanley. The deaths referred to "fever" last week were Hanley. 20, against 16 and 19 in the two previous weeks; 4 occurred in Bolton (equal to an annual rate of 1.1), 3 in Manchester and Salford, 3 in Leeds, and 2 both in Nottingham and in Liverpool. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had declined from 2810 to 2696 on the four preceding Saturdays, had further fallen to 2624 on Saturday last; 284 new cases of this disease were admitted to these hospitals during last week, against 284 and 336 in the two preceding weeks. The Metropolitan Asylums Hospitals contained 4 small-pox patients on Saturday last. Of the 1285 deaths registered in London last week, 288 were referred to pneumonia and other diseases of the respiratory system, against numbers increasing from 167 to 230 in the four preceding weeks; these 288 deaths were, 1 0 0 however, 3 below the corrected average number in the corre-1 0 0 sponding week of the five years 1904-08. The causes of 35, or

0.8 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered last week were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, Nottingham, Leicester, Salford, and in 50 smaller towns; the 35 uncertified causes of death in the 76 towns last week included 8 in Liverpool, 6 in Birmingham, and 4 in South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 794 births and 566 deaths were registered during the week ending Nov. 13th. The annual rate of mortality in these towns, which had been equal to 12.9 and 15.3 per 1000 in the two preceding weeks, further rose to 15.8 in the week under notice. During the first six weeks of the current quarter the annual death-rate in these Scotch towns averaged 13.7 per 1000, and exceeded by 1.0 the mean rate during the same period in the 76 largest English towns. The annual death-rates last week in these Scotch towns ranged from 8.5 and 12.9 in Perth and Aberdeen, to 17.6 in Paisley and 18.0 in Glasgow. The 566 deaths from all causes in the eight towns last week showed a further increase of 19 upon the numbers returned in the two preceding weeks, and included 66 which were referred to the principal epidemic diseases, against 34 and to an annual rate of 1.8 per 1000; the mean rate from the same diseases last week in the 76 English towns did not exceed 0.8 per 1000. The 66 deaths from these diseases in the Scotch towns last week included 22 from measles, 16 from diarrhea, 10 from scarlet fever, 7 from diphtheria, 6 from "fever," and 5 from whooping-cough, but not one from small-pox. The 22 fatal cases of measles in the eight towns were within two of the number in the previous week; 21 occurred in Glasgow. The 16 deaths attributed to diarrhosa exceeded by 3 those returned in the previous week, and included 7 in Edinburgh, 5 in Glasgow, and 2 in Dundee. The 10 fatal cases of scarlet fever showed a considerable increase upon recent weekly numbers, including 7 in Glasgow and 2 Edinburgh. The deaths from diphtheria, which had been 4 and 13 on the two previous weeks, declined last week to 10, of which 4 occurred in Glasgow, and 2 in Aberdeen; 5 of the 6 deaths referred to "fever," and 3 of the 5 fatal cases of whooping-cough were returned in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 68 and 108 in the two preceding weeks, further rose last week to 115, but were 11 below the number registered in the corresponding week of last year. The causes of 18, or 3.2 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,142,308 persons, 564 births and 420 deaths were registered during the week ending Nov. 13th. The mean annual rate of mortality in these towns, which had been equal to 14.8, 16.4, and 17.4 per 1000 in the three preceding weeks, further rose to 19.2 in the week under notice. During the first six weeks of the current quarter the annual death-rate in these Irish towns averaged 16:4 per 1000, whereas the mean death-rate during the same period did not exceed 12.7 in the 76 largest English towns, and 13.7 in the eight principal Scotch towns. The annual death-rate last week was equal to 21.7 in Dublin (against 13.9 in London, 17.5 in Belfast, 20.5 in Cork, 12.1 in London-derry, 20.5 in Limerick, and 21.4 in Waterford; the mean rate in the 16 remaining smaller Irish town districts last week was equal to 17.9 per 1000. The 420 deaths from all causes in the 22 town districts last week showed a further increase of 39 upon the numbers in the three preceding weeks, and included 20 which were referred to the principal epidemic diseases, against 26 and 21 in the two previous weeks; these 20 deaths were equal to an annual rate of 0.9 per 1000; in the 76 English towns the rate last week from the same diseases was 0.8, and in the eight Scotch towns was 1.8 per 1000. The 20 deaths from these epidemic diseases in the Irish towns last week included 9 from diarrhoa,

5 from whooping-cough, 3 from "fever," 2 from diphtheria, and 1 from scarlet fever, but not 1 either from measles, or smallpox. The 9 deaths attributed to diarrhoea showed a further decline from recent weekly numbers, but included 4 in Dublin and 2 in Belfast. The 5 fatal cases of whooping-cough corresponded with the number in the previous week; 4 occurred in Belfast, and 1 in Dublin. Of the 3 deaths from enteric fever 2 were recorded in Belfast and 1 in Dublin. A fatal case of diphtheria was returned both in Dublin and in Belfast. The deaths resulting from pneumonia and other diseases of the respiratory system, which had been 50, 60, and 86 in the 3 preceding weeks, further rose to 88 in the week under notice. The causes of 16, or 3.8 per cent., of the deaths in these Irish towns last week were not certified by a registered medical practitioner or by a coroner; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.8 per cent., and in the eight Scotch towns the proportion was 3.2 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Fleet-Surgeons: V. G. Thorpe to the Terrible and J. F. Hall to the Terrible, for medical charge on passage home from Colombo. Staff-Surgeons: M. P. Jones to the Hogue, on commissioning; M. C. Langford to the President, additional, for service at Medical Department, Admiralty; A. W. B. Livesay to the Devenshire; and J. O'Hea to the Terrible and to the Powerful, on recommissioning. Surgeons: W. K. D. Breton to the Terrible and to the Powerful, on recommissioning; H. C. Devas, A. A. Sanders, K. H. Hole, H. F. Briggs, and W. Miller to the Viotory; H. W. Nicholls, R. P. M. Roberts to the Wildfire; G. F. Syms, M. P. Fitzgerald, J. Hadwen, J. S. Orwin, and J. Barrett to the Vivid; G. A. Jackson and A. G. Malcolm to the Pembroke, all additional, for disposal.

The undermentioned Staff-Surgeons have been promoted to the rank of Fleet-Surgeon in His Majesty's Fleet: James William Wilcocks Stanton, Thomas Dufour Halahan, John Christopher Durston, Morris Charles Langford, Percy Hamilton Boyden, Alfred Hutton Jeremy (dated Nov. 14th, 1909).

The undermentioned Surgeons have been promoted to the rank of Staff-Surgeon in His Majesty's Fleet: Ernest Fitzgerald Ellis (dated Feb. 11th, 1909), Pierce Leslie Crosbie (dated Sept. 23rd, 1909).

ARMY MEDICAL SERVICE.

Surgeon-General William Donovan, C.B., retires on retired pay (dated Nov. 17th, 1909).

ROYAL ARMY MEDICAL CORPS.

Colonel E. Butt has been appointed Principal Medical Officer, Presidency and Assam Brigades, vice Colonel J. G. Harwood, retired. Lieutenant-Colonel R. H. Firth, in charge of the School of Army Sanitation, Aldershot, has been gazetted Brevet-Colonel, under the terms of the Royal Warrant (Articles 35 and 307), for distinguished services of a scientific nature in connexion with sanitation. Lieutenant-Colonels H. Carr, J. V. Salvage, and Major R. F. E. Austin on arrival from England have been appointed to command the station hospitals at Jullundur, Ferozepore, and Jutogh respectively. Lieutenant-Colonel T. Daly and Major H. N. Dunn have been appointed to command the Station Hospitals at Dalhousie and Dagshai respectively from March 1st, 1910.

INDIAN MEDICAL SERVICE.

Colonel R. W. S. Lyons has been appointed Officiating Principal Medical Officer, Kohat Brigade. The services of Captain Macrae have been placed temporarily at the disposal of the Jail Department of Eastern Bengal and Assam. Captain E. W. C. Bradfield has been appointed to the permanent medical charge of the 31st Lancers. Captain A. E. J. Lister, at present in permanent medical charge of the 5th Cavalry, has been selected to succeed Major K. Cameron, R.A.M.C., as staff surgeon, Army Headquarters, Indian Major Bruce Seton, secretary to the Director-General, Indian Medical Service, has been selected as the Government of India representative on the Simla Municipal Committee, vice

Colonel Watkins. Captain R. McCarrison has been appointed agency surgeon at Gilgit. Captain Hepper has been posted to Peshawar as plague medical officer. Lieutenant James is provisionally promoted Captain. The services of Captain K. S. Singh have been placed at the disposal of the Government of the Punjab.

SPECIAL RESERVE OF OFFICERS. Royal Army Medical Corps.

Supplementary List:—The undermentioned Lieutenants to be Captains: Robert A. O'Donovan (dated Sept. 24th, 1909) and Robert J. Stirling (dated Oct. 1st, 1909).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd Home Counties Field Ambulance: Hector Graham Gordon Mackenzie to be Lieutenant (dated Oct. 20th, 1909).

1st North Midland Field Ambulance: Henry Gray Woodhouse Dawson to be Lieutenant (dated Oct. 7th, 1909).

1st London (City of London) Sanitary Company: Lieutenant Ralph H. B. Carthew resigns his commission (dated Oct. 14th, 1909).

Attached to Units other than Medical Units.—Captain John Rowan to be Major (dated Dec. 27th, 1908).

DEATHS IN THE SERVICES.

Deputy-Surgeon-General James Edward Scott, late A.M.D., on Nov. 7th, in Dublin, aged 84 years. He entered the service in June, 1847, was promoted surgeon in February, 1856, and surgeon-major in June, 1867. He served with the Rifle Brigade in the Kaffir war of 1852-53, including the expedition beyond the Kei in August, 1852, and the final clearing of the Waterkloof (medal). He embarked with the Rifle Brigade, and served throughout the Eastern campaign of 1854-55 as surgeon of the 41st Regiment (medal with four clasps, the Fifth Class of the Order of the Medjidieh, and the Turkish medal). He retired in 1879.

THE RED CROSS SOCIETY IN ESSEX.

The Lord Lieutenant of Essex has been asked by the Red Cross Society to form a branch of the society in the county of Essex, the immediate object of which is to organise voluntary aid detachments for service in the county with the Territorial Forces in the event of invasion. Lord and Lady Warwick have been appointed Presidents of this branch of the Red Cross Society, Colonel R. B. Colvin will act as county director pro tem., and there will also be an honorary secretary. A large number of ladies and gentlemen are being invited to become vice-presidents, and to subscribe for local requirements. Voluntary aid detachments are needed to complete the organisation of the Terri-torial Royal Army Medical Corps, and it is proposed to raise one or more detachments (male and female) in each police division of the county, and where local recruiting committees for the county Territorial Forces already exist. The following are qualified to join voluntary aid detachments at once:—1. Registered medical practitioners of both sexes. Fully trained hospital nurses.
 Trained pharmacists.
 Those of either sex possessing first-aid and home-nursing certificates of the St. John Ambulance Association. The St. John Ambulance Association will give instruction and grant certificates in the last-named subjects in localities where their branches are formed-viz., Leyton, East Ham, Becton, Walthamstow, Ilford, Barking, Manningtree, and Colchester. In other places where no branch exists they will grant certificates to persons presenting themselves for examination on payment of a fee of 1s. per head. It is hoped that the Essex Educational Committee may arrange lectures on the above subjects. A voluntary aid detachment will consist of men and women under their own officers. The officers of the women's portion will be men but they will have also lady super-intendents. A detachment will number at least 88 persons, i.e., 18 officers and four women officers, 48 men and 18 women, or 66 men and 22 women all told. Each detachment will be divided into two half-detachments composed of men and women. Each detachment should be selfsupporting, and it is estimated that a small fee will be required from members of voluntary aid detachments to provide the necessary equipment and fees, which will be supplemented from the funds of the Essex Red Cross Branch. Detachments will be mobilised when occasion requires and members receive the pay of their respective ranks. Application should be made to either Colonel Colvin, C.B., Hunting.

Monkhams, Waltham Abbey, or Lady Warwick, at Easton Lodge, Dunmow.

THE JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the November issue of this journal Lieutenant-Colonel R. J. S. Simpson, C.M.G., R.A.M.C., continues his interesting medical history of the South African War. Among the other articles is one by Colonel T. M. Corker, A.M.S., who writes on War Training. In his introduction he says: "The suggestion that knowledge of military strategy on our part is uncalled for and unnecessary has been most unacceptable to our officers in the past. There is no phase of our work more important than that which yields positive proof of the great part the corps plays in the success of military operations-by clearing the area of conflict of the wounded that would hamper the movements of the general officer commanding-in-chief, and by dealing with them in such prompt and capable fashion that the dreadful sights of ancient battlefields may no longer horrify the eye and lower the morale of the rest of the Lieutenant-Colonel R. H. Firth, R.A.M.C., deals with the constitution, duties, and equipment of sanitary companies of the Territorial Force, and makes some suggestions for the best means of utilising the annual period of training.

UNITED STATES NAVAL MEDICAL BULLETIN.

The quarterly bulletin which is issued by the Bureau of Medicine and Surgery "for the timely information of the Medical and Hospital Corps of the Navy" embodies matters relating to hygiene, tropical and preventive medicine, pathology, laboratory suggestions, chemistry and pharmacy, advanced therapeutics, surgery, and other things of interest to the service. Among the interesting notes in the issue for October, 1909, is a case of fracture of the skull and gunshot wound with recovery. There is also an article on typhoid fever advocating the use of external cold and the copious use of water irrigations of the colon in preference to repeated bathing as being better suited to the conditions of the American naval service.

AN ITALIAN ORDER FOR A NAVAL SURGEON.

Staff-Surgeon Elystan Glodrydd Evelyn O'Leary, R.N., who is at present serving on H.M.S. Donegal at Devonport, has received the Italian Order of St. Maurice and St. Lazarus. Staff-Surgeon O'Leary was on the Sutlej, which was at Messina at the time of the earthquake.

SPANISH RED CROSS SOCIETY.

The Spanish Red Cross Society has issued an urgent appeal for assistance to enable it to continue its work in the Riff. The resources of the society have been greatly taxed, and it hopes that its good work may not be interrupted by lack of funds. Subscriptions will be gladly received by the British committee of the Spanish Red Cross Society at 6, St. Swithin's-lane, London, E.C.

ENAMINATION FOR COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS.

An examination for not fewer than five commissions in the Royal Army Medical Corps will be held on Jan. 26th next. Application should be made to the secretary, War Office, London, S.W.

THE TUBERCULOSIS EXHIBITION IN LONDON.-The Tuberculosis Exhibition of the National Association for the Prevention of Consumption, which was opened last summer at Whitechapel by the Right Hon. John Burns, M.P., and which has since been seen at the White City, will shortly be revived in the West of London. From Nov. 23rd to Dec. 4th inclusive it will be situated at the Chelsea Town Hall, under the auspices of the boroughs of Chelsea, Fulham, and Westminster, and from Dec. 8th to 17th inclusive it will be held as the Paddington Tuberculosis Exhibition at the Congregational Hall, Queen's Park, Harrow-road (by permission of the Rev. Dr. Lawson Forster). instances admission will be free and special popular lectures will be given on different phases of tuberculosis and its prevention. Amongst the lecturers who have already promised to speak at Chelsea are Dr. Arthur Latham, Professor G. Sims Woodhead, Dr. C. Theodore Williams, Dr. Hector Mackenzie, Mr. Stanley Bates, Dr. M. S. Paterson, Dr. Nathan Raw, Mr. Ainsworth Wilson, and Mr. William

LUNG PUNCTURE.

To the Editor of THE LANCET.

SIR,-In an article in THE LANCET of Nov. 6th on "Lung Puncture: a New Application of Clinical Pathology, Dr. T. J. Horder recommends the use of this procedure in "any case yielding signs of consolidation of the lung, in which careful examination of the sputum fails to reveal the nature of the disease," in cases of lobar pneumonia, "if the desired clinical course is departed from in any way to the prejudice of the patient," and finally in cases of abscess of lung or of bronchiectasis for the purpose of obtaining the causal organisms unmixed with the flora of the sputum. Details of six cases are given in which valuable information was gained from the fluid withdrawn from the lung by a hypodermic needle. Dr. Horder does not, however, mention certain grave risks which are apt to attend exploratory puncture of the lung. There are now on record a considerable number of cases of death following this procedure, some immediate and others within a few hours or days—deaths undoubtedly directly referable to the puncture. The writer has recorded three cases: in one, death occurred immediately on the puncture of the lung; in the other two cardiac inhibition occurred, but the heart's action was restored, death, however, occurring in three and five days respectively, the patients remaining unconscious the whole time.

Sir Thomas Oliver² has recorded two cases, in one of which death was instantaneous, and in the other occurring on the day following the puncture. In a third case severe symptoms with cyanosis occurred, but the patient rallied in two days. Dr. J. H. Wilks' recorded one with instantaneous death, associated with hæmorrhage into lungs and stomach. Dr. J. Porter Parkinson recorded one in which death occurred within two minutes, but at the post-mortem examination the stomach was full of blood and some blood was present in the bronchi. Dr. G. Carpenter 5 recorded one in which the stomach was found to be full of blood and the bronchi contained blood-stained mucus. Dr. J. M. Fortescue-Brickdale 6 recorded another fatal case, and Dr. H. Armstrong one in which recovery occurred after a grave attack of syncope. My colleague Dr. W. S. Colman tells me of another unpublished case in which death occurred five hours after the puncture and was associated with cyanosis and collapse. Finally, in one unrecorded case at St. Thomas's Hospital the puncture was performed under chloroform with instantaneous death on the introduction of the needle. Doubtless other cases have occurred, but the above series of 11 deaths is enough to show that real danger attends this apparently simple procedure. In some cases death is instantaneous and must be attributed to inhibition of the heart. It has been shown that stimulation of the pulmonary fibres of the vagus can produce an active inhibition of the heart.8 and this has been confirmed by Capps and Lewis in the case of experimental irritation of the inflamed pleura in

In the cases of Carpenter, Wilks, and Porter Parkinson the stomach was found to be full of blood and the bronchi to contain blood-stained mucus. In these cases the fatal result is probably attributable to hæmorrhage, though the possibility of the death being due to primary cardiac inhibition and the hamorrhage merely the result of the active compression of the punctured lung during the artificial respiration has to be entertained. In only two cases with severe symptoms did recovery occur. The very large number

of fatal accidents that have occurred during lavage of the pleura in cases of empyema are presumably of similar origin. Accidents have also occurred in aspiration of pleural effusions, but there seems to be much less risk in simple puncture of one pleural surface than in puncturing inflamed lung tissue.

The explanation of the occasional occurrence of this accident is far from obvious; it may be that the vagus fibres are unduly sensitive in these cases of inflammation of the lung and pleura, but it is difficult to understand why it occurs in some cases and not in others. It might be thought that the risk would be diminished by an anæsthetic, but, as noted above, one death occurred whilst the patient was under the influence of chloroform; it might, of course, be attributable to chloroform syncope, but the symptoms occurred immediately on the introduction of the exploring needle. Cardiac inhibition occurring during puncture of lung or lavage of pleura is one of the most fatal accidents met with in medicine, and artificial respiration, combined with other methods of resuscitation, have proved unavailing in the large majority of cases. The writer is of opinion that the method of treatment that offers the best chance of success is to open the abdomenand perform massage of the heart by the subdiaphragmatic route, and that this should be done within two or three minutes of the cardiac arrest and should be carried on concurrently with artificial respiration.

Even in those cases in which the heart-beat has been restored death has occurred in some cases after a periodvarying from hours to days, the patient never regaining consciousness; full details of two such cases are given in the paper referred to above. Numerous cases of this condition are on record in the literature, associated with lavage of the pleural cavity. In these cases it must be assumed that the brain has not been able to recover from the long arrest of its circulation. It is possible that cedema of the brain occurs and lumbar puncture would be worth a trial in any future In some cases exploratory puncture of the lung is unavoidable and the risk of cardiac inhibition must be taken; but it would be advisable to warn the patient and the patient's relatives that the procedure is not devoid of danger. This accident is of such an appalling character that its importance is utterly disproportionate to its doubtless small percentage incidence, and, in the absence of measures which may minimise the risk, seems to render inadvisable the routine use of lung puncture as a clinical diagnostic procedure—a procedure which, as Dr. Horder has clearly shown, would otherwise yield the most valuable information.

I am, Sir, yours faithfully. Upper Wimpole street, W., Nov. 7th, 1909.

To the Editor of THE LANCET.

SIR,-Referring to Dr. J. M. Fortescue-Brickdale's letter in your issue of to-day, in which your correspondent alludes to certain cases of rapid death following puncture of the lung, may I point out that there can be no greater risk of such an unusual calamity occurring after lung puncture than after any negative pleural puncture? In my article on Pleurisy in "Allbutt's System" I have dealt with these cases, and I have there pointed out that in all operations, however trivial, there is the possible contingency that the patient may die suddenly. And considering the great frequency with which a negative paracentesis thoracis is performed, it can scarcely be said that this contingency is more than the rarest of events.

Dr. Christian Simpson refers to the suggested treatment of chronic pneumonia by puncture of the lung. With treatment, however, my article did not deal, but with diagnosis. I therefore made no reference to Dr. Macalister's paper. ought, however, to have referred to an important article which appeared in The Practitioner for May, 1908, by Dr. J. C. Briscoe and Mr. E. U. Williams, on "The Treatment of Pulmonary Affections by the Inoculation of Vaccines," for in this article the authors draw attention to the information which may be gained from puncturing the lung in unresolved pneumonias. This I believe to be the first general reference to the method. My earlier communication in January, 1907, only related one specific instance of diagnostic lung puncture.

Since my article was sent to THE LANCET I have read the report of a communication made by my colleague Dr. W. H.

Willcox to the Belfast meeting of the British Medical Association on the Vaccine Treatment of Pneumonia. In this paper Dr. Willcox also makes a reference to lung puncture for purposes of diagnosis, and suggests the injection of a little sterile broth into the lung before withdrawal of the lung juice.

I am, Sir, yours faithfully,

Harley-street, W., Nov. 13th, 1909. THOMAS J. HORDER.

APPENDICITIS WITH HÆMATURIA.

To the Editor of THE LANCET.

SIR,—Your notice of this condition in THE LANCET of Nov. 6th, and the subsequent letter of Mr. W. B. Cosens in last week's issue, have interested me considerably, as the association of hæmaturia with appendicitis has been noted by me on several occasions, and, indeed, I have referred to its possibility in discussing the diagnosis of appendicitis in the fifth edition of Rose and Carless's "Manual of Surgery" issued in 1905. I am able to call to mind two patients who were lying in adjacent beds in hospital suffering from appendicitis who both had developed hæmaturia; one was a lad with a recent attack, the other a man who had sustained many attacks and whose appendix was enclosed in a dense mass of adhesions which on operation rendered its removal impossible. believe the source of the trouble is usually to be attributed to the fact that in these cases the appendix is adherent to the posterior abdominal wall over the line of the ureter, and I attribute the hæmaturia to a ureteral source and not to the kidney. In support of this idea I might mention a case which occurred to me some years back. I was called one evening to see an adult woman who was suffering from the most typical and intense renal colic. There had been a previous history of pain on the right side, which might have been of renal, biliary, or appen-dicular origin. For this she was treated, and the passage of some gravel seemed to alleviate the symptoms.
The attack therefore seemed probably due to the impaction of a calculus in the ureter, but the most careful investigation was made with a view to inclusion or exclusion of the appendix as the source of the trouble. Radiography was not existent at that time, and finally I cut down on the kidney to find a healthy organ with no sign of calculous disease and a pervious normal ureter. The pain continued subsequently and the patient died a week later from perforation of an appendix abscess, the appendix being located in the back of the abdomen and just hanging down over the pelvic brim in the situation of the ureter.

I am, Sir, yours faithfully,

Upper Wimpole-street, W., Nov. 16th, 1909. ALBERT CARLESS.

THE INFLUENCE OF MIND AS A THERA-PEUTIC AGENT.

To the Editor of THE LANCET.

SIR,—I have read with interest your special article on the above subject in THE LANCET of Nov. 6th, reporting Dr. Claye Shaw's address and the subsequent discussion. I was also present at the Harveian Society when the address was given and the discussion took place. The address itself was comprehensive, philosophical, and suggestive of many trains of thought which might have been developed. The discussion contained little philosophy, if I may express myself so without offence, but was certainly very "practical." That is to say, it sufficiently demonstrated the fact that some practitioners had found that, by soothing some nervous patients with and without a certain amount of manual mystery, annoying and painful symptoms had in some cases been relieved and bad habits in some instances corrected.

The thesis, however, that the mind has a therapeutic influence under certain circumstances scarcely required a full-dress debate for the establishment of a fact so commonly observed and, I had thought, so generally admitted. For, surely, the acknowledged fact that emotional disturbances have a morbific influence involves as a corollary that the removal of emotional disturbance has a therapeutic influence. It was generally agreed that suggestion was of little value in the treatment of insane patients. But it was not pointed out that the supervention of insanity might itself be on occasion a therapeutic

agent, although the induction of such a condition by suggestion, were it possible, would scarcely be proposed as a beneficent measure! For example, a case was brought to my notice some years ago in which a lady suffering from heart disease and subjected to much domestic unhappiness lost compensation, had progressive cardiac failure, became dropsical, and was at the point of death. At this stage she lost her reason and became oblivious to her sorrow, soon afterwards recovering cardiac force, when all the evidences of her circulatory failure disappeared. The disturbing mental factor had been tragically eliminated and some of its consequences vanished. But the "sweet oblivious antidote" was in this was in this case obtained at terrible cost. The tragedy, however, some hypnotists would say, might have been avoided. For the 'rooted sorrow" of an unfaithful husband might have been plucked from the poor lady's memory and left her heartwhole, smiling on Lothario. I understand that amnesia may be permanently limited by suggestion. Surely a most beneficent power in a world of regrettable incidents, even though one live thereafter in a hypnotic and hypothetical

Reference was from time to time made in the discussion to the prejudice entertained by the profession against the suggestive or hypnotic treatment of disease. I confess, Sir, that I number myself with those who regard this prejudice as altogether wholesome, and trust I may still regard myself as not singular. There are doubtless a large number of neurotic persons of somewhat unstable mental equilibrium whose stability may in addition have been rendered still more unsteady by drugs, drunkenness, or excess of other kinds, and who may thus become, for the time at all events, incapable of listening to and being influenced by reason. Where emotions are concerned reason is not always in the ascendant. If such persons, under the spell of the stronger personality of the suggester—a factor to which some importance appeared to be attributed—are capable of being restored to greater equanimity and good conduct, I presume no one can offer any objection to the employment of such beneficent suggestions, whatever form they may take, and whether induced by means of the hand of the operator laid on the pit of the stomach, as one of the speakers said was his wont, or without any such manœuvre.

But, Sir, there are many cases, even among the unstable, which benefit by the plain if sympathetic inculcation of common sense, the inspiration of righteous conduct, and, above all, of courage to face and to accept whatever betide:

"Felix qui potuit rerum cognoscere causas ; Atque metus omnes, et inexorabile fatum Subjecit pedibus, strepitumque Acherontis avari !"

Some years ago I had occasion to see a lady who suffered from time to time from severe fits of a hystero-epileptic character for which I could do little until I discovered that the underlying cause of her disturbance was the sufficient fact that she loved one man and had been persuaded to contract what was regarded as an advantageous marriage with another. I then pointed out to her the alternatives to accepting the situation with resignation as an honourable woman, and was struck by her telling me, ten years later, that she had never had a fit since the conversation which I held with her, when her position and duty became more clear to her.

"Whether 'tis nobler in the mind to suffer The slings and arrows of outrageous fortune, Or to take arms against a sea of troubles And by opposing end them,"

is a quandary in which the patient often finds himself, and not an unhopeful mood for the physician to find him in, provided he can induce him, according as his condition is incurable or curable, to do the one or the other with open-eyed courage and a full appreciation of the circumstances. He may then be placed in the way to establish that equanimity or insouciance which brings in its train, sometimes slowly, but often surely, quietude, normal sleep, refreshment, and in the case of functional disorder frequently "cure," while in the case of incurable disease he is thus placed in as favourable a position as possible; and, if in pain, he may gain ease by that which produces sleep, not hypnosis. But it is by the straightforward exercise of sympathy, common-sense, reason, and knowledge that we can best foster such recuperation, aided, it may be, in the case of those addicted to drugs or drunkenness, by a period of self-imposed incarceration under circumstances in which the exercise of a besetting propensity

is difficult, and this without a lunatic conception of what may be a beverage of extremely good vintage, or at the expense of the reputation of a very useful drug. That in these days of specialism the fostering of health-giving mental impulses should be erected into a speciality is not surprising, but I would submit that such specialisation is quite uncalled for, as some who took part in the debate on Dr. Claye Shaw's address fully recognised.

In some cases, I imagine, not even a physician is necessary, and perhaps, after a preliminary examination by a competent medical man, a certain number of cases might be relegated to the "Christian Scientists" for treatment as a change from the once more popular nursing homes for neurasthenics. But your leading article in THE LANCET of Nov. 6th sufficiently indicates that a preliminary consultation with the faculty should take place before the patient is placed, as Mr. Stephen Paget seems to suggest he might in some instances be, on the list for Christian Scientist "treatment," if the patient have a bias towards that mode of therapeutic effort or consolation. So much might perhaps in the present day be conceded to poor souls shaken for the time in a steadying faith by that too iconoclastic materialism preached so blatantly by some aggressive physicists of the nineteenth century, whose "cocksureness" the opening twentieth the opening twentieth century is inclined to regard as somewhat premature and which it will probably, as it grows older, be glad to forget, like Huxley's "Bathybion Haeckeli" on the strength of which scientific error Strauss died an atheist.

In his broad consideration of the whole subject, one the importance of which I in no way desire to depreciate and myself emphasised in an address on the Place of Metaphysics in Medicine, on which you at the time commented in The Lancet, Dr. Claye Shaw has touched, on the one hand, on the foundations of religious faith and, on the other, on the practical application of suggested belief in the treatment of disease. Much as one is tempted to follow him into the former sphere the pages of a medical journal are scarcely suited for discussing the questions involved. I, therefore, refrain from doing so, merely remarking that the foundations of religious belief are nothing if not historical, and that the Way and the Life are alike uninteresting if divorced from the simple and unvarnished Truth, whether suggested or entertained. imagine the same criterion should determine what is and what is not permissible in therapeutic methods. The whole purpose of this letter is to question alike the desirability of, or necessity for, the employment of make-believe, or placebo, in the treatment of disease under any circumstances, except, perhaps, in our dealings with some lunatics and the obsessed by a notion, when the physician may be compelled, distastefully to himself, to use argument on the mental plane of the afflicted or adopt subterfuge to effect goodin other words, in the portico of the lunatic asylum. Finally some remarks were made in the discussion on the suggestive nature of the action of drugs. There have been, and no doubt are, some drugs in use the direct potency of which for therapeutic purposes is not great. But, surely, it is not necessary to insist that a large proportion of the most useful drugs are as potent for evil as for good unless used with a skill which it is open to all to acquire, and in securing the beneficial results of which the mental processes of the patient have little share.

I had written so much of these remarks when THE LANCET of Nov. 13th reached me, in which I observe your leading article on the Therapeutics of Suggestion and Dr. Mercier's paper on Brain and Mind, both of which bear upon the subject. I am glad to read in the former that a preference appears to be expressed for that better way in which "no part of the patient's personality is suppressed or placed in abeyance, but an appeal is made to the crowning function of all the functions—namely, the mind by careful methods of rational persuasion" (p. 1447). For such I have contended in this letter and confess that, to my mind, to support and form the character of a humanity, which has to face the many insoluble problems of an infinite universe as well as the vicissitudes of life in health and in disease, more is to be gained even from the hopeless but brave attitude of the Stoic who exclaimed, "Thou canst not rob me of death!" than from the position occupied by those who are lulled into peace by any species of make-believe, and under such circumstances necessarily live with some part of their being in abeyance, notwithstanding argument to the contrary.

But were we to accept Dr. Mercier's conception of the relation of mind to brain possibly there might be less objection to suggestive therapeutics. So far as I can gather his meaning, the mind as an "epiphenomenon" has ceased to have material connexion with the cells from which it sprang, and the rearrangement of its processes by hypnosis would only be to play among immaterial atoms. I do not know in how far such a view will be acceptable to the majority of present.day physiologists and psychologists. But it is because I believe now, as I did when I delivered my lectures on the Relation of the Nervous System to Disease and Disorder in the Viscera in Edinburgh in 1898, "whether the registration of memory be in the cell or merely rendered possible through the instrumentality of the cell that it would be impossible without the cell, and that the passage of impressions through the cell influences the organic conditions of the latter" (p. 49), that I conceive there is objection to methods which tend to cause us to look on matters not as they are but as they are not. Hypnotists tell us that this may be brought about without detriment to the mental organism. Can it occur without change in the mental organ? And if not, is such change desirable or safe?

Sir, it is because I venture to question this that I look upon the therapeutic trilogy of "Christian Science," Hypnotism, and the isolation Nursing Home as in the same category, and of these upon hypnotism as the most objectionable. The "Christian Scientist," so to speak, hypnotises himself or attempts to do so, the Somnambule is hypnotised, the Segreyé, to coin a convenient term if it is not already in use, is advised to regard vacuity and frequently to overeat himself, which latter has the merit at times of recalling him to earth by dyspepsia if by no other means. The full influence for good of the mind upon the body may, however, I maintain, be procured by fostering the courageous outlook of the open-eyed whole man upon all that can befall him and by the aid of agencies which import no spurious or supposititious conditions. But the task of those who take this view is not rendered easier by the creation of therapeutic sandheaps such as those discussed, in which distressed humanity is invited to bury its head like the ostrich, and thus to escape at least the vision of danger.

I am, Sir, yours faithfully,

Nov. 14th, 1909. ALEXANDER MORISON, M.D., F.R.C.P.

DARWINISM AND MEDICINE.

To the Editor of THE LANCET.

SIR,—In his recent Bradshaw lecture Professor J. A. Lindsay, referring to the changes which are taking place in the jaws and teeth of civilised man, says: "Apparently the diminution in the size of the jaws has outrun the diminution in the size or number of the teeth, and hence the overcrowded state of the jaws which we know to be so common." May I say that I have not been able to obtain any evidence in support of such a conclusion? In the absence of malformation of the jaws (e.g., from adenoids) overcrowding of the teeth is always, in my experience, due, not to any racial diminution in the size of the jaws, but to arrested development of the jaws from disuse in the individual. In other words, provided the young human is brought up on food which demands a due exercise of the muscles of mastication overcrowding (with the exception mentioned) never occurs.

And now I would like to refer to a subject which is of the utmost importance to biologists. Professor Lindsay very truly remarks that "man is not subject to the unrestrained operation of natural selection." He does not, I am interested to note, maintain that this process has ceased to operate on civilised man. Yet this is what many leading biologists are now doing. So careful a thinker as Professor Arthur Thomson in his philosophical Bross lectures (1907) writes: "We can never resume the yoke of natural selection which even early man began to wriggle out of, which man has been more and more effectively throwing off as the ages have passed." In support of this view he proceeds to cite Professor Ray Lankester: "The mental qualities which have developed in man have to a large extent, if not entirely, cut him off from the general operation of that process of natural selection and survival of the fittest which up to their appearance has been the law of the living world. Nature's

¹ The Bible of Nature. Charles Scribner's Sons, New York, 1908.

inexorable discipline of death to those who do not rise to her standard—survival and parentage for those alone who do-has been from the earliest times more and more definitely resisted by the will of Man;" and this authority goes on to refer to man's "rebellion against natural selection" and, again, to his emancipation from "the destructive methods of natural selection.

Is it not remarkable that two such eminent biologists should be so anxious to rebel against natural selection and to repudiate its aid? Is it not strange that they should wish to disown the golden ladder by which man has mounted from the beast and without which he must lose all hope of further ascent? For if there is one fact which stands out more prominently than another in connexion with organic evolution it is (whatever the mutationists may say to the contrary) that natural selection is indispensable to that evolution.

Fortunately there are no grounds for assuming that natural selection is ceasing to operate on man. In point of fact it is essential to the continuance of species, for without its operation it would be impossible for these to become adapted to those never-ending changes in environment which are inevitable in this world of mutation. Certain it is that without natural selection man could not have attained his present civilisation. The conditions of civilisation have for thousands of years been entailing changes in his environment, changes both material and psychic, and during all these years man has been undergoing adaptation to these changes under the beneficent sway of natural selection. This conclusion follows from the non-inheritability of acquired characters.

The important part played by natural selection in the case of man was worked out by me 20 years ago in my work on "The Causation of Disease," which was, I believe, the first systematic attempt to bring pathology into line with Darwinism. It is often wrongfully assumed that injurious conditions necessarily lead to racial degeneration, whereas, as a matter of fact, their effect is rather to start a process of adaptive evolution. In the work referred to I pointed out that whenever a community is subjected to a nocuous but not "necessarily fatal" influence (i.e., one which does not inevitably lead to total destruction) the process of racial-I use the word as opposed to individual—adaptation is at once started, and I emphasised the fact that all deaths from non-traumatic causes occurring before the end of reproductive life are instances of natural selection. This being so, we have only to reckon up the number of such deaths in any community in order to estimate the extent to which that community is being influenced by natural selection.

I have said that civilisation has brought with it many conditions which did not obtain in the case of man's primitive ancestors. These include conditions which we term unhygienic. It has to be remembered, however, that for Nature they are simply modifications in the environment, and she at once sets to work to secure a racial adaptation to them by natural selection, with the result that what was un-healthy yesterday may be healthy to-day. This important truth seems to have escaped the biologists, all too heedless of the teachings of pathology. Consider the enormous mortality of slum-bred children. What is this but natural selection working in tragic earnest? What is it but an effort of nature to evolve a slum race—a race that is adapted to the special dietetic and atmospheric conditions of the slums? And who can doubt that far from leading to racial degeneration its effect is rather to widen the range of man's resistance to environmental influences?

Just because man is not undergoing any obtrusive change in physical conformation it is assumed that he has come to a standstill. The fact is forgotten that a hidden invisible change may be quite as important as a gross organic one. Biologically speaking, the acquisition of subtle invisible mechanisms to cope with an invisible microscopic host is every whit as important as the development of horns or tusks to fight against a visible enemy.

Had I the time and space I might add many instances to the one I have given of the operation of natural selection on civilised man. I might instance the fact that every death from alcoholism is the elimination of one who is unfit as regards alcohol, and the further fact that drunkenness, far from injuring our race, is really purging it of undesirables.

I might further show that this same influence is still subtly

at work on the psychic side of man. I must, however, rest content with having emphasised the truth that man's destiny on earth is intimately bound up with the inexorable operation of natural selection—that process at once cruel, merciful, tragic, sublime.

I am, Sir, yours faithfully,

Wimpole-street, Nov. 7th, 1909.

HARRY CAMPBELL.

THE TREATMENT OF CHRONIC ULCER OF THE LEG.

To the Editor of THE LANCET.

SIR,—The views of Mr. Willmott Evans as to the frequency of a gummatous origin for these ulcers will doubtless be fully discussed by surgeons. My attention is confined to his remarks on the dry treatment of the ordinary ulcer. The absence of any reference to the "open" or "atmospheric" method would seem to imply that this plan does not occupy any prominent place in surgical teaching and practice. A few years ago, whilst studying the effects of the method of "Interrupted Circulation" in its application to chronic ulcers, I repeatedly noticed that after a period of most satisfactory and comparatively rapid progress the treatment lost some of its efficacy. It occurred to me to try the effect of keeping the ulcer continuously exposed to the air without any dressing. A single layer of gauze was spread over it as a protection, but without any contact with the granulations, whilst the remainder of the limb was kept under cover. The result was striking. The final closure of the small ulcer which had refused to heal was brought about within 24 hours. This method may probably have been applied before, though it was novel to myself. It is perhaps worthy of a more extensive trial by others.

I am, Sir, yours faithfully, WM. EWART.

Upper Brook-street, W., Nov. 15th, 1909.

To the Editor of THE LANCET.

SIR, -Mr. Willmott Evans, in his article in THE LANCET of Nov. 13th on the Treatment of Chronic Ulcer of the Leg, gives his opinion that more than 90 per cent of these cases are syphilitic in origin. Later on he remarks that the most important point in diagnosing chronic syphilitic ulcers of the leg is multiplicity. I agree with him that over 90 per cent. of multiple chronic ulcers of the leg are syphilitic, but I think it will be agreed that the majority of chronic ulcers of the leg are single, not multiple. Does Mr. Willmott Evans hold that 90 per cent. of single chronic ulcers of the leg are syphilitic? If so, I think he is considerably exaggerating the percentage. iderably exaggerating the first faithfully,

I am, Sir, yours faithfully,

C. F. Marshall.

Euston-road, N.W., Nov. 15th, 1909.

THE INFLUENCE OF DIET ON THE THYROID GLAND.

le the Editor of THE LANCET.

SIR,-I welcome the opportunity afforded me by Dr. Ernest Young's interesting letter in your issue of Nov. 13th of further referring to a point of some interest and importance in relation to diet and the thyroid gland. The salient feature in Dr. Young's letter is in the following passage: "While admitting without question that a diet which contains little protein may produce favourable results, I must confess to some scepticism as to the result being due to the influence of the diet on the thyroid gland. If this were so, then a diet consisting entirely, or almost entirely, of protein would, if I understand Dr. Watson rightly, have a converse effect upon the gland and so aggravate the condition, which is not so," and he invites me to explain the paradox. May I in the first place point out that Dr. Young has not rightly understood my position. This is no fault of his, however, but is due to the restriction of my original letter. The apparent paradox referred to by Dr. Young had not escaped my observation. On the contrary, for some years past I have made a special study of many cases of gouty disorders under my own care, in which I found it advisable to modify the diet in the direction of diminishing the carbohydrates and increasing the protein elements in the food. Dr. Young puts forward as an explanation of why a diet

approximating to a purin-free diet, and a common form of dist such as the exclusive meat diet are each capable of producing good results in gout, that both, if carefully regulated to the digestive capacity of the individual, tend to eliminate the chief causative factor—viz., auto-toxæmia. I am in complete accord with Dr. Young in thinking that intestinal derangement is the primary factor in gout. This view is one to which I have sought to draw special attention for many years past. At the same time I cannot agree with him in regarding it as in any way an explanation. When it is analysed it explains nothing. What we have to consider is the varying liability to certain types of intestinal derangement which we see as clinicians, and to ascertain so far as possible on what these depend.

My explanation may or may not be the right one; it is at any rate based on new facts obtained from experimental investigation. Briefly stated, my position is as follows. We have in gout a disorder of protein metabolism; the thyroid gland has long been known to be specially concerned in the metabolism of protein foods; my observations have shown that the structure and function of this gland are modified by diet, and specially that meat is primarily a stimulant and later a depressant of its activity; my clinical experience of gouty disorders is in harmony with that of those who find that in some cases a lacto-vegetarian diet and in other cases a diet rich in proteins is of special value in treatment; and I believe that the favourable effects of the dietetic treatment in both instances are due to a large extent to the influence of the diet on the thyroid gland. In the case of the lacto-vegetarian diet the strain on the gland is diminished by a marked reduction in the amount of proteins in the food; in the case of the rich protein diet the normal digestion and metabolism of the proteins are promoted by the fact that the farinaceous and other foods are restricted, and under these circumstances the stimulating effects of the diet on the thyroid gland assert themeclves with advantage to the patient.

I am, Sir, yours faithfully,

CHALMERS WATSON. Edinburgh, Nov. 14th, 1909.

THE TREATMENT OF UTERINE FIBROIDS BY X RAYS.

To the Editor of THE LANCET.

SIR,—I think the following case should prove of interest, showing, as it does, that fibroid of the uterus may be successfully treated by being subjected to the influence of X ravs.

A woman, aged 37 years, married, one child, came to me with the following history. Two years previously she had been curetted for the relief of menorrhagia due to a fibroid, but the relief obtained was only of a temporary nature. A year ago she again went into hospital with a view to operation. She was told, however, that the only cure would involve a removal of the uterus, and, failing that, the next best thing would be to curette again, the latter course being eventually carried out. I saw her for the first time about four months after she had been curetted and the monthly hæmorrhages were again becoming excessive. tried the usual routine treatment of ergot, hot douches, and rest, but with only moderate success, until finally her condition grew so grave that it became necessary to recommend operation. Before doing so, however, I determined to try the effect of treatment by exposure to X rays, and Dr. W. Ironside Bruce very kindly consented to carry it out. The fibroid at this time was of the size of a pigeon's egg and was situated in the anterior wall of the cervical canal. In view of the position of the tumour irradiation was carried out with the patient in the knee-elbow position, the rays being directed from below upwards in the axis of the pelvic brim; a filter composed of several lavers of felt was placed between the skin and the tube, thereby all risk of X ray dermatitis was obviated. Each irradiation lasted ten minutes, and three sittings were given in the week. The total time of irradiation amounted to 70 minutes in all, and the current used was from an 8-inch coil taking a primary current of 100 v. 5 amps. The tube was one with a water-cooled anode having an equivalent spark gap of from 4 to 6 inches. In short, the amount of current passed through the tube was just as much as could be passed through it for ten minutes without rendering it too soft to be

of any use. After the first sitting the patient complained of aching pain in the back, which lasted until after the fourth exposure. The menstrual period, which occurred about this time, was accompanied by severe loss, but she found that the discomfort which she usually experienced two days before the onset was very much improved.

At the conclusion of the sittings Dr. Ironside Bruce and myself again examined her. He could find no trace of growth and thought the cervix was normal. I thought I could still detect an ill defined thickening in the anterior cervical wall on the site where the fibroid had been. The day after the examination her period occurred at its proper time, and she noticed, firstly, that it began without any warning of pains or discomfort; secondly, that it lasted only three days, and that there were no clots or sudden gushes so noticeable on previous occasions; and thirdly, that on its cessation she felt perfectly well and fit to carry on her household duties instead of feeling a wreck for a day or so as she had always done before. Only 12 towels were used instead of the usual 27 or 30. Previously to irradiation the patient had been much troubled by a leucorrheal discharge; she tells me now that this is scarcely noticeable. - I am, Sir, yours faithfully

URQUHART BARTHOLOMEW, M.R.C.S. Eng., L.R.C.P. Lond., L.M.S.S.A. Lond.

Green-street, W.C., Oct. 30th, 1909.

THE NATIONAL ASSOCIATION FOR THE FEEBLE-MINDED.

To the Editor of THE LANCET.

SIR,-Thank you very much for the notice you have inserted in THE LANCET re the annual report and conference, but you have omitted to make any mention of the Princess Christian's Farm Colony which we have just opened near Tonbridge, a beautiful property of 171 acres. We hope that on this colony houses will be erected for men and women, boys and girls, and also a school for children; although only half the farm is occupied by us at present, we can already house 30 boys, and are making immediate arrangements for the alteration of the present buildings so that they will accommodate another 20; it is hoped also that a home for girls will very shortly be taken in hand.

I am, Sir, yours faithfully, A. H. P. KIRBY, Secretary. Denison Heuse, 296, Vauxhall Bridge-road, S.W., Nov. 8th, 1909.

THE NATURE OF OSTEITIS DEFORMANS (PAGET) AND ITS RELATION TO MALIGNANT NEOPLASIA.

To the Editor of THE LANCET.

SIR,-In endeavouring to determine the natural relations of a novel morbid condition for which a definite place has not yet been found in our nosological cadres a great deal depends on the standpoint from which the pathologist surveys the scene.

Having for many years taken special interest in "osteitis deformans" (Paget), chiefly with the object of determining its inter-relations with malignant neoplasia, it will perhaps interest your readers to know the conclusion at which I have arrived, after having studied the malady from this somewhat unusual standpoint. It will be remembered that three of Sir J. Paget's five cases were complicated by malignant neoplasia, and so many other examples of this concomitancy have since been reported that the impression has arisen that this form of bone disease is often complicated by malignant tumour formation. This being so, I was much surprised on going over the records of over a thousand consecutive cases of primary malignant tumours to find that not a single one of them was complicated with "osteitis deformans." In endeavouring to unravel this puzzle I was led to pay particular attention to the precise seats and nature of the tumour lesions in cases of this concomitancy, and it then became manifest that these affected chiefly the skeletal bones, and that they were generally described as being of "sarcomatous" nature, many of them having a myeloid structure.

From these and other converging indications of like import

I became convinced that the neoplastic disease not uncommonly associated with "osteitis deformans" is something quite distinct from the ordinary carcinoma and sarcoma. Further examination of the ensemble of the subject in this light convinced me that the real affinity of the concomitant tumour disease in these cases is with "multiple myeloma," and I finally concluded that "osteitis deformans" is the outcome of a bone-marrow disease, akin to "multiple myeloma" in its minimal form, whether associated with albuminosuria

In conclusion, I think it would be as well if future investigators of "osteitis deformans" were to conduct researches along the lines I have indicated, as a new vista would thus I am, Sir, yours faithfully,
W. ROGER WILLIAMS. be opened up.

Nov. 13th, 1909.

VOLUNTARY WITHDRAWAL FROM THE MEDICAL REGISTER.

To the Editor of THE LANCET.

SIR,—During the last ten years or so a certain number of applications have been made to the General Medical Council by medical men for permission to withdraw their names from the Register. In all cases, so far as I am aware, the requests have been granted, and the matter has attracted little or no general attention, despite the fact that each recurring instance has necessitated the devising of a special fashion of dealing with it. Neither the making nor the granting of such applications was anticipated by the framers of the Medical Act of 1857, so the Standing Orders of the Council likewise contain no reference to them. rise of this practice led last year to the appointment of a committee of the General Medical Council to consider the best procedure for its regulation, and the committee's report was received at the beginning of the last session of the Council. The recommendations in this report, so far as they have been made public, consist mainly of a rule drafted by the legal adviser to the Council and submitted for inclusion among the general Standing Orders of the Council. This order appeared in the record of the proceedings of the Council published in THE LANCET of May 29th (p. 1572) and runs as follows: "Every application by a registered medical practitioner or dentist for the removal of his name at his own request from the Medical or Dentists Register shall be accompanied by a statutory declaration to be made by the applicant, that he is not aware of any proceedings or of any reason for the institution of any proceedings which might result in establishing cause for the erasure of his name from the Medical or Dentists Register without his consent, or for depriving him without his consent of any qualification or licence entitling him to be registered.' The report was received and entered on the minutes, and there the matter presumably will rest until next session. Meantime, however, it seems desirable to direct attention to certain sides of an interesting question, and to consider the motives which may lead a medical practitioner to seek to have his name erased from the Register.

The reason of the existence of the Medical Register is to enable persons in need of medical assistance to distinguish between qualified and unqualified practitioners. anyone, having once obtained a place on the Register, want to be erased from it? Churchill's excellent Medical Directory and the handy smaller directory published by Nisbet are not in the same position as the Medical Register, and one can see reasons why a medical man not in practice might desire to remove his name from these books. They give much fuller and sometimes more accurate information about medical men than appears in the official list, although this is not in the least the fault of the Registrar responsible for the compilation of the latter. The directories are concerned with more than bare registration, and even in matters of titles may be more accurate than the Register, for the additional fee demanded for the registration of qualifications subsequent to those which have placed a name upon the Register leads a good many medical men to keep that publication in ignorance of their complete professional status, whereas the medical directories are regularly informed on all such matters by the owners of the included names. The result is that a man who has retired from practice, or has never been in practice, may find it inconvenient to have his name in the medical directories. He may

not wish to be known by his neighbours as a medical man, since it may lead to his being worried for advice which he is not prepared to give, or he may not wish to have his letter-box filled with circulars and advertisements, as are those of most practitioners whose addresses appear in Churchill's Medical Directory

But no such reasons apply to inclusion in the Medical Register, a volume which conveys no information to any one beyond the fact that the bearers of certain names. who live at certain addresses, have obtained qualifications which legally entitle them to practise medicine and surgery if they think fit. It is not easy, then, to see why any medical man having once been on the Medical Register should desire to conceal the fact. He may not want to secure the advantages of being on the Register, but he can dispense with them by discontinuing practice. The advantages are not really great. A man on the Register can sign death certificates, can hold appointments established under authority of an Act of Parliament, and can sue in courts of law for fees due for medical attendance given and medicaments supplied. But in the present state of the law a man not on the Register is perfectly free to attend as many patients as he pleases, so long as he does not pretend to registration; he could even hold appointment on the staff of any voluntary hospital, whose managers might be sufficiently ill-advised to accept his medical services. He cannot sue for fees; but therein he is no worse off than men of the consultant class, whom custom forbids to resort to the law in search of payment for services rendered. He cannot sign death certificates, but there are many paths of medicine in which the need of them rarely arises. The members of the medical profession in the Cavendish-square district do not sign collectively as many death certificates in a year as are given from a small general hospital. From all this it appears to follow that the disabilities attendant upon voluntary withdrawal from the Register are not great, but neither are the inconveniences of remaining on the Register even when an intention not to practise makes such privileges as pertain to registration quite valueless.

I do not wish to reflect in the slightest degree on any man who up to the present has withdrawn his name from the Register; there may be perfectly good reasons for adopting that course in some instances. But consideration of the facts stated above make it quite clear that in other instances the voluntary withdrawal from the Register may mean merely an unhealthy dislike to the jurisdiction of the General Medical Council. To practise medicine without being on the Medical Register is perfectly easy—all that is needful to render the unregistered man safe is that he should not pretend to registration—and to conduct such practice without fear of the disciplinary interference of the General Medical Council might be very convenient.

I am, Sir, yours faithfully, DISCIPLINE.

ON RADIUM IN THE TREATMENT CANCER AND SOME ASSOCIATED CONDITIONS.

To the Editor of THE LANCET.

SIR,-Having considered from a bird's-eye point of view Mr. H. T. Butlin's article published in your issue of Nov. 13th, in the first place my attention is attracted by the note that a patient "had to pay 2000 francs (£80) for his ten days' treatment in Paris.'

This reminds me that over 30 years ago I heard a very wealthy physician casually remark one day that a guinea was a very large sum of money. It is useful to indulge the idea that such is the case, because in the hands of misers the solitary guinea might in time to come increase to millions. And so with regard to cancer. Surely Sir William Gull was astute when, in 1874, he remarked before the Pathological Society that "a cell is an organism of enormous extent; it is only our eyes being so feeble that makes us look upon it as a small indifferent thing. It may be infinitely more delicate than those great things which we see under the microscope, even though it be the fifteth of an inch in diameter." The whole tenor of Mr. Butlin's article and general views leads me to think that he appreciates this. He will not hesitate to pronounce a growth

of very small size to be a cancer and knows that the disease may originate from a solitary leucoplakic spot. Then as to treatment, the reported cases seem to show that the employment of radium has not proved curative in cases of cancer of large dimensions, say the size of a small apple and upwards, but when open to easy inspection cancer ought to be diagnosed often when no larger than a pea, and the assistance of the microscope must not be under-estimated. Whilst therefore I have not gathered that radium has yet proved of great service in the treatment of advanced cancer, I venture to think that it may be claimed to have cured already many cases in which the diagnosis was clear, and though the growths were small yet had they been allowed to proceed untreated they would certainly have followed the usual natural history and destroyed life.

It would therefore seem that the use of radium may be relied upon in the treatment of cases of small cancer, and the use of the knife perhaps be rationally superseded. To expect that radium may cure a cancer the size of a cocoanut is perhaps expecting at present rather too much. Having said what I have, I cannot conclude this letter without remarking, with your kind permission, that in many small cases where radium might be successful perhaps the use of a solution of bichromate of potash might answer equally well. I also believe that a small spot of leucoplakia, which if untreated might develop into cancer, may be successfully

cured by painting with carbolic acid.

I am, Sir, yours faithfully, CHARLES E. JENNINGS.

Great Somerford, Wilte, Nov. 15th, 1909.

MEDICAL EXAMINATION OF TERRITORIAL RECRUITS.

To the Editor of THE LANCET.

SIR,-It is quite clear from the question addressed in the House of Commons to the Secretary for War by Mr. Fletcher regarding the pay of officers of the Royal Army Medical Corps (Territorial Force), that the medical department of that branch of the service is in a very unsatisfactory state. A medical officer assures me that his expenses at camp this year, arising from locum-tenent's fees and board, professional losses through absence, mess expenses, tips, and disallowed claims, amounted to £36 15s. Against this there is pay £18, leaving a balance to the bad of £18 15s. As regards this officer's kit, his very moderate claim for out-of-pocket expenses is not settled yet, and in addition there are about £20 due to him for the examination of recruits.

As one reads Mr. Haldane's carefully written answer to Mr. Fletcher's question one cannot help feeling that the Secretary for War is actually making an ad miscricordiam appeal for release from a monetary obligation. The answer is saturated with mendicity. I do not hesitate to say that if this officer's claim be not allowed ne will be fully justified in regarding his services as having been extorted under false pretences and in shaping his action accordingly. is action accordings.
I am, Sir, yours faithfully,
BETA,

Nov. 15th, 1909.

SMALL-POX IN TURKEY.—An alarming epidemic of small-pox is raging at present in different towns of the Turkish provinces. It seems that this epidemic began in Smyrna, where many victims are dying daily. From the accounts that have reached Constantinople, it is evident that the small-pox cases are of the hæmorrhagic type. A family who to escape the epidemic removed to heres carried the contagion there, with the result that a number of people died from small-pox. News comes from Salonika and Adrianople that an outbreak of the epidemic is raging there also. It seems that the authorities are inactive and are taking no preventive measures. Adrianople is only just rid of an epidemic of scarlet fever. The sanitary conditions of that town are anything but satisfactory. All this, of course, contributes to spread the epidemic of small-pox. In the above-named towns the schools have been closed and the hospitals are overfilled with patients. An outcry of complaint is being raised against the authorities of the large Jewish school of Adrianople, which has more than 500 children, and which did not close its doors in time. Help is

being asked urgently from Constantinople.

THE HOUSING PROBLEM AT BUDAPEST.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

WHAT THE CONGRESS DID NOT SEE IN 1894.—BUDAPEST AS THE MOST OVERCROWDED CITY IN EUROPE.—
MODERN SANITARY IMPROVEMENTS AND A REDUCED DEATH-RATE.—CELLAR DWELLINGS.—NEGLECT OF THE HOUSING PROBLEM.—FAILURE OF PRIVATE ENTER-PRISE.—FEEBLE EFFORTS OF THE STATE AND THE MUNICIPALITY.

AFTER the Eighth International Congress of Hygiene and Demography which met at Budapest in 1894 I investigated the housing of the poor in the Hungarian capital. During the Congress we had been shown everything that was to the credit of the town, but we were left to find out the dark corners for ourselves. This led me to write some articles entitled, "What the Congress did not See," and to raise the question as to what was the true function of such a Congress. For instance, the next International Congress of Hygiene is to meet in 1910 at Washington. Should the organisers of that Congress endeavour to show their visitors only what may elicit praises of the sanitary progress achieved in the United States? Or should they, on the contrary, profit by the presence of distinguished foreign authorities to show the defects that still exist, and strengthen the home demand for reform by the denunciations the foreign critics would not fail to pronounce? The latter obviously is the least pleasant but the most useful course to pursue. As the condition of affairs in Budapest in 1894 was very bad some strong denunciations were greatly needed. At that time and at the Congress Dr. Bertillon stated that, according to the stati-tics for the year 1891, the proportion of overcrowded houses or lodgings in Paris amounted to 14 per cent., in Berlin and in Vienna to 28 per cent, in Moscow to 31 per cent., and in St. Petersburg to 46 per cent. For Budapest Dr. Bertillon's figures dated back to 1881 and then the over-crowding was 71 per cent. The one excuse is that Budapest claims to be the Chicago of Europe by reason of the rapid increase of its population. From 1801 to 1891 the population increased on an average 37.7 in Lordon, 38 1 in Paris, 53 9 in Vienna. 70.7 in Glasgow, and 90.7 in Budapest per 1000 per annum. Nevertheless, the fact remained that whereas great efforts had been made to build magnificent and palatial houses overlooking broad thoroughfares, little or nothing had been done to provide suitable dwellings for the poorer section of the community. Many Hungarian medical men were most anxious that this cruel neglect should be denounced in the strongest terms, and therefore I visited, photographed, and described some of the homes of the Budapest poor. These articles were translated into Hungarian and led to some stormy debates in the municipal council of Budapest. By one party I was denounced in very strong language, while the other party declared that I had rendered great service in thus bringing home to the population and their representatives how urgent was the need of energetic measures in regard to the housing of the poor. To-day, however, both sides in this controversy have to acknowledge that by such stimulation some improvement has been effected, though it is in regard to housing that Budapest still remains one of the most backward of the large towns of Europe.

An excellent pocket "Medical Guide to Budapest" was issued for the use of the members of the Sixteenth International Medical Congress, edited by Dr. Tibor de Györy. In this is a short chapter on the housing question that fully confirms what I had said 15 years ago. For instance, the lack of cheap dwellings is explained in the following manner :-

The evil dates back to the epoch when Budapest emerged at a bound from comparative littleness into the circle of the great cities. With the regulation of the city the desire to build expensive modern houses found free scope. In place of old small houses in which the poorer classes found cheap dwellings, palaces have arisen whose expensive dats are for the better classes alone.

Thus the rents of tenement dwellings rose higher and higher until the conditions have become almost unbearable. As cheap lodgings cannot possibly be obtained it is necessary

¹ See THE LARCET of Jan. 5th, 1895, p. 55, and Jan. 19th, p. 172,

Ł

to take in, not merely sub-tenants, but even bed tenants, of which the Medical Guide to Budapest says:—

Conditions thus arise which, considered in their sanitary or moral aspects, are alike revolting - conditions which neither the willingness of the authorities to make sacrifices nor the erection of spacious emergency dwellings has, so far, been able to obviate.

To what extent overcrowding prevails may be gathered from the statement that during the last decade there were 9518 rooms occupied by 77,696 tenants. This meant that 10.8 per cent. of the then population of Budapest lived four, or more than four, in a room. For statistical purposes, living four in a room is qualified as overcrowding, though it seems to me there may be very serious overcrowding when only two or three persons live in a room, for it all depends on the size of the room. Thus defined, the proportion of overcrowding during the previous decade amounted to 13.2 per cent. Therefore it is claimed that however bad the situation still remains there has been some improvement. In one respect I am glad to record there has been a considerable amelioration. What impressed me most painfully in 1894 was the great number of cellar dwellings, and these were situated not merely in poor quarters but in some of the very finest streets of the capital. In Magyar-street I found wine-cellars converted into dwellings, places where there was no light whatsoever, and others where the only light admitted came from a small opening on a level with the causeway of the street not two feet high and about three feet broad. In those days the Director of the Statistical Office at Budapest, the well-known demographer, Dr. Körösi, had calculated that human life was on an average shortened from two to three years by living in cellars, and that epidemic diseases were 60 per cent. more frequent in these under-ground places. Yet of the tenement dwellings of Budapest ground places. no less than 5.09 per cent. were mere cellars.

As already observed, it is in the abolition of cellar dwellings that the greatest progress has been achieved. The medical guide-book quoted above states that in 1880 there were 5217 cellar tenements with 31,637 occupants, and states that to-day there are only 1672 such tenements remaining and that they have not more than 8083 occupiers. This shows that some energy has been displayed, but also that the good work is not yet fully accomplished. The necessity of absolutely forbidding anyone to sleep in close contact with the soil is all the greater, as on the Pest side of the Danube this soil is often very foul; it is made up of rubbish thrown down to fill up hollows where water used to stagnate. The late Dr. Joseph Fodor, in his advocacy of sanitary reform, analysed the soil and found that 0.778 per cent. consists of organic matter. The Museum Boulevard, where the Congress of Medicine met, stands on an ancient cemetery, and the Rostély and Terez streets have similar sites

Besides the reduction of the number of cellar dwellings, very great increase has taken place of late years in the construction and in length and number of sewers. At the same time, the quality and amount of the water-supply has likewise been considerably augmented. The drinking water supplied in the year 1874 was estimated at 3560 cubic metres, or 31 litres per day and per head of the population. In 1907 there were consumed 62,079 cubic metres, or 212 litres per day and per head. Then, again, the sanitary services, though still very much undermanned, have been far more energetic of late years. Prophylactic measures against epidemics are imposed with much greater Then many efforts have been made to keep the houses and streets clean and to disinfect when necessary. The supervision of the food-supply, though altogether insufficient, is very much better than it used to be. There is a more general medical supervision, medical aid is more readily forthcoming, and hospital accommodation has been much increased. Thus the deaths from infectious disease, which increased. Thus the deaths from infectious disease, which amounted to 4 67 per annum per 1000 of the population 30 years ago, are now only equal to 1.6 or 1.8 per 1000, while small pox has been almost completely eradicated. all these considerations must be added the fact that while, as a couse pience of immigration from the country, the population of Budapest has greatly increased, the birth-rate has decreased during the last 30 years from 44 or 45 per 1000 per annum to 27 or 28 per 1000. Finally, it must be horne in mind that a large proportion of the inhabitants of Budape-t are not people who spend all their lives there but adults who come to work during the prime of their lives, just

at the time when death is least likely to occur. Therefore, and in spite of the overcrowding of tenements, which still constitutes a great grievance, the general death-rate has greatly decreased of late years. In 1874 it was as high as 42.2 per 1000. Then some sanitary measures were taken into consideration and slight improvements attempted. Ten years later the mortality had fallen to 30.6 per 1000, but in 1886, in consequence of the cholera, it rose to 37.7 per 1000. In 1890 the death-rate was 29.2 per 1000, and it gradually fell to only a little above 20 per 1000.

In dealing with the chief of remaining defects, the overcrowding of dwellings, the authorities at Budapest are not in a worse position than other communities, on the contrary, they have facilities enjoyed by few towns. There is no fixed boundary, no fortifications like the walls of Paris, to prevent expansion. Of far greater importance, there is no land difficulty. At Budapest the land belongs to the town. It is true that during the last 30 years some of this land has been sold by the municipality for absurdly small sums where it has not been given away. But the municipality still holds a great part of the land, and now realises how important it is not to sell or give away so valuable a public asset. In most countries, but in England especially, the great difficulty is to obtain land at sufficiently cheap rates for it to be possible to build tenement houses that could be let out at low rates. At Budapest not only does the municipality already possess a large quantity of land, so that there is no necessity to create a sinking fund to pay off a loan for the purchase of land, but there are also special laws favouring the building of artisans' dwellings. First, an effort was made to encourage private enterprise. Regulations proposed by the municipality were confirmed by a decree issued by the Minister of the Interior in 1892. This by-law exempted small dwelling houses built outside the Great Boulevard, if they had no cellars or any subtenants, from local taxation for 10 years. Further, if any contractor built 60 such houses he would be able to obtain the land from the municipality at a reduced price. Workmen's lodgings generally would be free from local taxation for 15 years if there were no cellars and no subtenants, and after that no local taxation should exceed 10 per cent. of the rateable value. If a new house was built and two-thirds of the house consisted of small lodgings of one or two rooms and no inhabited cellars it would be exempt from taxation for 20 years. Special advantages also are given to building societies.

With all this encouragement it was thought that many private individuals would speculate in the production of workmen's dwellings, and that large firms would also build for the workmen in their employ. The result has been most disappointing. Little or nothing has been attempted by private enterprise, and the State has also been very slow to move. But it became more and more evident that if anything was going to be done the State and the municipality must set the example. The administration of the State railways therefore built small houses on an estate in the outskirts of Budapest where a considerable number of railway servants are comfortably housed. Then there are Government factories at the village of Kispest, about half an hour from Budapest, where the Government has built seven houses with eight tenements in each house and intends to provide for a population of 2000 in all; but this work is going forward very slowly. Turning from the State to the local authorities, it may be mentioned that throughout Hungary and Croatia there are 72 comitats or county councils, and only 10 or 12 of them are attempting to deal with the housing question, and they have as yet built but very few workmen's dwellings. Thus in the provinces the progress is as slow as in the capital, for if in its turn the local authority at Budapest has entered the lists and has built some municipal tenement houses, these were only inaugurated on August 1st last, just in time to show the Medical Congress that something

These dwellings I was able to visit during the month of September, that is, after they had been occupied for a little while. They are at a considerable distance from the centre, and in so isolated a position that there is no medical practitioner at hand. Three deaths had already occurred among the children of the incoming tenants, and the fact that it was necessary to send a long distance for medical assistance was found to be a great hardship Doubtless, in time, when more houses are built and more pe ple live here, some enterprising practitioner will come and reside in the neighbourhood. The

municipal tenements consist of large four-storey blocks built on each side of a square which is being laid out as a garden and playground, so that both adults and children will be able to enjoy some relaxation in the open air. Though the design of the buildings is very simple, nevertheless the gloomy barrack-like appearance of many such structures has been avoided. The wide and light arch of the open-air staircases, and above all the high and pointed roofs of coloured tiles give a certain brightness and variety of form and colour which produces a cheerful impression. As inside everything is quite clean and fresh, for it is all so new, this impression is not effaced on penetrating among the inhabitants of the tenements. The lofty pointed roofs form large attics where the inhabitants can hang their clothes up to dry. The washing is done downstairs in the basement. Here are numerous store-houses for wood and other fuel. Then there are hot and cold baths and the necessary conveniences for washing the family linen. The tenants take it in turn to make use of these appliances.

finished. It is to be hoped, however, that greater care will be shown in regard to the sanitation of future tenements, for the new municipal tenements which I visited, though so clean and fresh, had no provision made for the ventilation of the rooms. There were only windows, and these could not be opened partially at the top so as to provide a little ventilation without causing too much draught. Nor were there any small holes pierced in the walls to let a little air through when both doors and windows are shut. Again, there is only one water-closet for every two tenements. Here instead of a large window opening on to the outer air there is a small window giving on to an inner shaft about 3 feet square. This shaft is too small to let down any light, and in the absence of any artificially induced current takes up little air, so that the closet, which ought to have the maximum supply of pure air and light, is always in darkness and is but very feebly ventilated. As compared with the older models of artisan dwellings built in England, the tenement dwellings of the Budapest At present there are only 166 tenements ready for municipality are much more artistic and cheerful in form, habitation, and this is not enough to attract a medical colouring, and decoration, but they are decidedly inferior

The Budapest Municipal Tenement Dwellings, opened August 1st, 1909.

practitioner. When the temporary school now installed in from the sanitary point of view to anything which could now one of the blocks of buildings is removed to a school which is to be provided there will be 192 tenements available. Also the municipality has built close by a row of small shops, and these add a little to the population while supplying the daily requirements of the inhabitants. The tenements consist some of one room and a kitchen, with antechamber; others of two rooms and a kitchen and an antechamber. The rents for the tenements with but one room vary from close upon £8 to £12 10s. per annum; and those with two rooms, kitchen and antechamber are rented at £16 12s. to £20 per annum. Dear as this may seem, it is nevertheless cheaper than the usual charge made. At Budapest a small unfurnished room and kitchen can be rented at £16 10s. to £20, and two rooms with an antechamber and kitchen in the centre of the city would cost £58 per annum. Even at these exorbitant rents there were only 127 houses empty in Budapest last quarter. There has been very little building during the last few years, though the demand for house room is ever increasing. But now, what with State and municipal enterprise, 3000 to 4000 new tenements will be available when the constructions either just completed or actually in hand are all quite

be built in England.

In one other respect, bearing on the housing question, Budapest is most unfortunate. The tramway companies not only charge very high fares but stop running early in the evening. This renders it very inconvenient to live in the suburbs, increases the congestion in the centre, and prevents the expansion of the city. At Huddersfield many years ago the town council ran a tramway up a hill to a very healthy outlying site where there were hardly any inhabitants. was obvious that this would be a dead loss, and It so it was for a time, as there were hardly any passengers in the tramcars, but it helped to relieve the congestion in the centre and was the means of ultimately bringing into existence a very desirable and healthy suburb. At Budapest the tramways belong to two private companies that are not animated by any such public-spirited Nor do the complaints of the inhabitants have policy. much effect, and it is stated that certain members of the municipal council are directors or large shareholders of Also anyone at Budapest these tramway companies.

connected with a newspaper receives a free pass and travels gratuitously on the tramways. From all of which it somehow happens that pressure is with difficulty brought to bear on the tramway companies. Nevertheless, the question of cheap, constant, and easy transport is very intimately connected with the housing problem and the want of healthy dwellings at moderate rents is the most urgent need of the population of Budapest. On this I very forcibly insisted 15 years ago after the Eighth International Congress of Hygiene and Demography. While gladly recognising that in the interval some progress has been accomplished, it is still on this, the housing difficulty, that I must again insist to-day after the Sixteenth International Congress of Medicine.

MALARIAL FEVERS IN INDIA.

REPORT ON THE CONFERENCE APPOINTED BY THE GOVERNMENT OF INDIA.

(From a Special Correspondent.)

(Continued from p. 1470.)

The Address by the Lieutenant-Governor of the Punjab, So.

FOLLOWING the addresses delivered by his Excellency Lord Minto and Colonel Leslie, I.M.S., Sanitary Commissioner with the Government of India (see p. 1483 of our present issue), Sir Louis Dane, Lieutenant-Governor of the Punjab, a most able administrator who has spent his whole career and service in the Punjab, made a very effective appeal to the Congress. After first thanking the Viceroy for summoning such an influential Congress to deal with what he considered perhaps the most important sanitary and administrative question in India, he passed on to review the occurrence of malarial fevers in his own province. He said that the Punjab had bulked largely in Colonel Leslie's paper, and perhaps, as head of this province, he might be allowed to add a few words on the general question before the Conference proceeded to attack it in detail. It is a curious fact that in the Punjab, when they were involved in epidemic disease, the results are ordinarily more strikingly disastrous than elsewhere. This holds good especially in the case of malarial fever. It had been his good fortune to have spent most of his service amongst the people as a district and settlement officer and he could speak with full knowledge of the terrible ravages that malaria caused. Epidemics of small-pox, cholera, and plague are grievous afflictions, but neither singly nor even collectively are they responsible for so much economic inefficiency, and, what is worse, actual human misery as the recurrent scourge of malaria. To cope adequately with this curse of the country had been his chief endeavour since he assumed charge of the Punjab Government. Colonel T. E. L. Bate, M.A., I.M.S., and Colonel G. F. W. Braide, I.M.S., would explain what measures the Punjab Government had adopted and how far they had been successful. was confident that the results of the deliberations of this Conference would materially help him in his task. It was a curious fact that most of the severe epidemics of malaria in recent years in the Punjab with which he had been brought into personal contact had been associated with a cataclysmal downpour of rain in the months of July and August, and it was perhaps a still more curious fact that the epidemic had almost synchronised with the downpour, as Colonel Leslie had noticed. He remembered the heavy rains of 1880 and the resultant epidemic in Amritsar, when that unfortunate city lost 15,000 people in 3 months from malaria. In 1890 there was heavy rainfall in the Punjab submontane tracts, and the high uplands of Gujarat, Sialkot, and Gur-daspur districts were decimated. This tract is singularly dry and free from stagnant ponds, and no doubt the question of why fever should have visited it in such a way will be duly considered. In 1892 he was in Peshawar. It was thought that the dreaded Peshawar fever had died out owing to sanitary improvements and the introduction of a pure watersupply. In July and August of that year they had 20 inches of rain, against an average of perhaps 2, and this was followed by an appalling outbreak of the worst type of Peshawar fever, and the returns of the army will show how the troops suffered. Our experience of last year had been noticed by Colonel Leslie, but it was very similar. He

ventured, therefore, to suggest for consideration why such outbreaks follow so closely upon these downpours. There must be other causes than those mentioned by Colonel Leslie, and if the Congress could discover them it will have done well indeed by the Punjab. He concluded his remarks by again thanking the Viceroy for his gracious action in convening this conference, from which all hoped so much for the country and its peoples.

Summary of Transactions.

Major S. P. James, I.M.S., introduced a discussion upon the Distribution of Malaria in India, and dwelt upon the necessity for an investigation similar to that which Captain Christophers made in the Punjab, which should be begun in every province. He said that many people still believe that anti-malarial measures were required almost everywhere in India, and that for this reason the magnitude of the task was to be measured only by the area of the country and the number of the inhabitants. There were still people who go to the trouble of working out the cost of distributing quinine to the whole population of a province. Such calculations serve no useful purpose, and the appalling figures which result from them tend to discourage effort. But if, instead of proceeding to ascertain the magnitude of the task by such methods, an attempt were made in the first place to define the exact distribution and comparative prevalence of malaria in the province, the result might quite possibly show that the expense of dealing with the disease would be only moderate in comparison with total revenues of the province. For example, even a cursory examination of the death-rates from fevers in the Madras Presidency indicates that the areas in which measures are urgently required cannot be numerous, and that the task of dealing sufficiently with malaria in this Presidency may be by no means one of great magnitude. Indeed, if we assume that, at any rate, for a number of years all our efforts should be concentrated upon the mitigation of malaria in places where such efforts are urgently required, and he took it that this meant in places where the disease was seriously interfering with prosperity and with the natural increase of population, he doubted if there were half a dozen considerable areas in the Madras Presidency which would come in that category. Again, it is, or was until quite recently, a common belief that Assam as a whole is intensely malarious, but the truth is that a great part of that country is only very slightly malarious, and that in some areas the disease does not occur. He believed the same may be true even of a country with so bad a reputation for malaria as Burma. Major James also referred to the necessity of ascertaining for as many areas as possible in each province what proportion of deaths recorded under the heading "fever" by the existing agency for the collection of vital statistics are due to malaria, and he suggested a series of careful inquiries by a professional agency in selected areas of every province.

Captain S. R. CHRISTOPHERS, I.M.S., read a paper on a New Statistical Method of Mapping Epidemic Disease, with Special Reference to Malaria, and confined himself to a discussion of the returns of the Punjab. He said that the mortality statistics of the Punjab were capable of telling us a great deal regarding the incidence of the epidemic disease, and that in arriving at this information the method of using an epidemic figure had its uses. In the case of great epidemics a rough notion of their distribution could be gained even from applying this method to district tetals, but to ascertain with any delicacy the distribution of these epidemics, it was necessary, for reasons explained, to resort to thana figures or even for certain purposes to the returns of individual villages.

Major W. H. KENRICK, I.M.S., civil surgeon of Khandwa, drew attention to the risks that were run by travellers in resthouses, paraos or halting-camps, and large junctions on main lines of traffic. Such places, he held, form a perpetual source of malarial infection; and persons halting at them do so under conditions most favourable to the anopheles mosquito. He drew attention to the fact that the great majority of malaria cases, especially those of a severe or persistent type of fever, give a history of having acquired the infection while in the district away from their headquarters town. A European is called upon to leave his headquarters on a short tour of duty. He spends a few nights in a certain dâk bungalow or rest-house, and within three weeks of his return he develops an attack of fever. With natives it is

generally the result of stopping the night at some parao or generally the result of stopping the night at some purus or rest-camp or at some village dharmsala while on a journey to or from his home. This is the usual cause of an attack of malaria; very few cases are of indigenous infection. He suggested that in each district a list of the more unhealthy parass could be maintained and operations commenced upon each in turn with a view (1) to destroy mosquitoes and larvæ and get rid of their breeding grounds; (2) to render the wells mosquito-proof; and (3) to issue quinine free to the local inhabitants and to place it at all times within their reach free of cost. These operations should result in lessening the infectivity of such places, not only for malaria but to a certain extent for cholera. He then referred to the fever-rate in Pachmarhi. At that hill station the admission rate of European troops for intermittent fever in 1907 was 654 per 1000, while the rates at Saugor, Jubbulpore, and Kamptee were 286, 161, and 149 respectively. Natives also suffer severely from malaria in Pachmarhi, while European officers and ladies are comparatively free from the disease. The reason for this is that the soldiers and nearly all the natives break their journey at the foot of the hill at a place called Singanama, which is teeming with mosquitoes and exceedingly malarious The inhabitants of Singanama and the neighbouring forest villages suffer to a large extent from chronic malaria and enlarged spleens; they live under conditions most favourable to the factor of residual infection. The mosquito finds unlimited breeding grounds and a constant supply of food; thus every opportunity exists for persons halting for a few hours after sunset in the parao to acquire the infection. They get an attack of malarial fever within two or three weeks subsequently, and accuse the hill station of being malarious. It was obvious that larvicidal operations at Pachmarhi can be of very little use so long as the source of the malaria is left untouched, and Major Kenrick urged that the destruction of the mosquito must first be carried out in the places which he instanced as centres of infection. He set forth a very strong case, and it is to be hoped that systematic efforts will be made to render halting places and camps less malarious by attacking the breeding grounds of the mosquito.

Colonel W. G. KING, I.M.S., gave an account of the malarial operations undertaken in Madras and Burma, and matters connected with the same subject as it affected British cantonments in India were dealt with by Colonel J. THORNHILL, Indian Army, Inspecting Officer of Cantonments. Major J. CHAYTOR WHITE, I.M.S., advocated the introduction of small fish into tanks and catchment areas for the purpose of destroying mosquito larvæ, and referred to the good results said to have been effected by the use of fish (millions) for this purpose in the West Indies.

(To be continued.)

BRISTOL AND THE WESTERN COUNTIES. (FROM OUR OWN CORRESPONDENTS.)

The School of Medicine, University of Bristol.

YET another student association has come, or rather is coming, into being; it has been decided to try to organise a clinical society, primarily for the students, but also for the teaching staff of the faculty of medicine and for old students of the Bristol School of Medicine. This will, it is hoped, do as much good for the Bristol school as the corresponding organisations have effected for the other medical schools in London and the provinces.—The annual medical school dinner will take place on Nov. 23rd, when Mr. C. K. C. Herapath will preside and Sir Isambard Owen, Vice-Chancellor, will be the guest of the evening.

Distribution of Prizes to Nurses.

Within the past few days the nurses at the Bristol General Hospital, as well as those at the Children's Hospital, have received the prizes and certificates for the past year's work. At both institutions this annual function is made the excuse for a pleasant occasion, committee, staff, and friends joining to show their appreciation of the work done by the nurses.

The Sanitary Inspectors' Association.

The annual meeting of the south-western centre of the Sanitary Inspectors' Association was recently held at Bristol. There was a good attendance, and Mr. E. J. Casely read an

interesting paper on the milk-supply of Bristol. He stated that Bristol was supplied with milk from 82 supervised farms within the city area and 300 farms outside such boundary. Mr. Casely advocated that every dairy farmer, dairyman, and purveyor of milk should be licensed, and he expressed the opinion that they would willingly pay a reasonable sum for the same. He also considered it important that the premises should be used for dairy produce only, and if the farmer, dairyman, or purveyor of milk did not comply with the regulations they should have their licences revoked and not allowed to trade.

British Red Cross Society.

Mr. J. S. Griffiths has been appointed county director of the British Red Cross Society for Bristol. He is deputy commissioner of the St. John Ambulance Association for the 15 southern and western counties and a member of the central executive committee.

Enteric Fever at Taunton.

At a meeting of the Taunton town council held on Nov. 9th the medical officer of health (Dr. H. J. Alford) reported that 11 cases of enteric fever had recently occurred in the town; the cases came from seven houses. It was stated that the water-supply of the town was above suspicion. On the recommendation of Dr. Alford the council decided to stop the milk-supply from a certain dairy in the town.

The Local Government Board and the Supply of Diphtheria Antitexin.

At the last meeting of the Keynsham (Somerset) district council a letter was read from the Local Government Board, in reply to the council's inquiry, stating that the Board would be prepared to entertain applications to sanction any reasonable expenditure which may be incurred by the council (acting upon the advice of its medical officer of health) in supplying diphtheria antitoxin to medical practitioners for use in its district.

Nov. 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Presentation to Emeritus Professor Crum Brown, Edinburgh.

ON Nov. 12th a gathering took place in the debating hall of the Edinburgh Students' Union of an interesting character. The meeting was held for the purpose of presenting Emeritus Professor Crum Brown with his portrait, which had been subscribed for by former students and friends of the Professor. The chair was taken by Professor James Walker and the presentation was made by Principal Sir William Turner, K.C.B. The Principal recounted the attainments of Professor Crum Brown and dwelt upon the services which he had rendered to the University during his long tenure of the chair of chemistry. The portrait is from the brush of Mr. E. A. Walton, R.S.A., and is both a good portrait and an excellent picture. Professor Crum Brown expressed his gratitude to the subscribers. The subscribers numbered 350.

The Royal Society of Edinburgh.

The new premises of the Royal Society of Edinburgh, which are situated in George-street, were opened formally on Nov. 8th in presence of a distinguished company. The occasion was used by the new President, Principal Sir William Turner, K.C.B., to give a historical résumé of the origin, development, and growth of the society. The new premises afford much more suitable and more ample accommodation for the society than the buildings on the Mound provided, which were occupied for so many years by the society.

The Abuse of Medical Charities in Scotland.

The report of the Commission upon the Scottish Poor-law has had publicity given to it by extensive quotations from it having appeared in the daily newspaper press. The parts of it which will most attract medical attention are those which deal with medical charities, especially in the large towns. In Edinburgh there has been a considerable amount of feeling amongst practitioners that our medical charities, and particularly the Royal Infirmary, were taken advantage of by persons quite able to pay for medical attendance at home

1550 THE LANGER, | SCOTLAND. [Nov. 20, 1909.

On this ground there has from time to time been a measure of agitation with a view to making the infirmary rules more stringent about the class of person admitted to any of its departments. So far this has not received much sympathy from the managers or from the honorary staff as a whole, and the last time the matter came up it was decided that the present evils were not comparable to the evils that would arise were a more inquisitorial system or a system of subscribers' lines introduced. Everyone recognises that there is abuse in some measure, greater in some special departments than in others, but it is held by some that it is not nearly so bad as is often represented. The Commissioners' report will bring this matter up again, for the report contains striking figures, while also showing that the amount of available gratuitous medical assistance is such that there is little attempt at providing for sickness by the provident system which is so widely used in England. The report says that 28 per cent. of the people in Edinburgh receive attendance from the medical charities of the city, and the other large towns in Scotland show much the same state of affairs. Were there to be a movement of any magnitude towards the establishment of a provident or cooperative system beyond what at present exists the practitioners would require to organise themselves so that their services were not obtained at an unjustly low price. The new Practitioners' Association of Edinburgh and Leith is the kind of local organisation that is likely to be of service to the medical profession at such a iuncture.

The Scottish Association of Medical Women.

The Scottish Association of Medical Women held its annual meeting in the Café, Edinburgh, on Nov. 13th, Dr. Elsie Inglis, the President, being in the chair. After the business of the year had been transacted by the council of the association and the balance sheet submitted and approved, a conference of Scottish medical women was held upon the difficulties that have arisen in connexion with appointments under school boards and public health authorities. A report was given by Dr. Mary Chalmers Watson, of the work done by the Information Bureau of the association in cooperation with the vigilance committee of the Registered Medical Women's Society, London, with the view of getting school boards and public health authorities to give equal remuneration to men and women medical officers. Dr. Louisa Garrett Anderson followed with an account of similar work done in England, and said that 18 posts had been dealt with in England where the salary offered to a woman for full-time work was less than that offered to a man; much valuable help had been given by Dr. Whitaker Smith and by the secretaries of the local branches of the British Medical Association, who had caused warning notices to be put into the Journal of the Association. After Dr. Anne Mercer Watson, had spoken, Dr. Isabella Mears addressed the conference upon the ethical aspect of the subject. She submitted that it was a strong temptation for medical practitioners to give too much of their services for nothing, but although money must never be put on the same plane as health, definite work should command a definite salary, and skill and experience receive adequate remuneration. Dr. Inglis closed the discussion, and the following motion was put to the meeting and carried

That this conference upholds and entirely approves the findings of the British Medical Association on the question of the remuneration of school medical officers—namely, that the minimum salary for full time work should be at the rate of £250 yearly, and that for equal work the remuneration for men and women should be the same.

Clinical Teaching in Glasgow.

The General Council of the University of Glasgow last week discussed the new scheme of clinical teaching which is being promulgated by the University Court with reference to the creation of chairs of medicine, surgery, midwifery, and pathology in connexion with the Royal Infirmary. On a vote being taken, after lengthy debate, it was ultimately decided by 31 votes to 10 to support the scheme. Later in the week the governors of the Victoria Infirmary met and issued a statement of their views on the subject. They understand that an essential part of the scheme is that the Muirhead trustees are to provide incomes for two of the four proposed chairs. This scheme, if carried out in connexion with the Royal Infirmary, must in their opinion inevitably place the Victoria Infirmary in an inferior position to the Royal Infirmary, and the tendency would be that physicians.

and surgeons of eminence and ability as teachers would prefer appointments at the Royal Infirmary rather than at the Victoria Thus the interests of the Victoria Infirmary Infirmary. would suffer. Patients also, when it became known that the posts in the Royal Infirmary were filled by men of the highest ability, would undoubtedly prefer to be admitted into the Royal rather than into the Victoria Infirmary, and donors would also be influenced unfavourably towards the Victoria Infirmary as regards the support of the two institutions. Hitherto, of the three great Glasgow hospitals, only one of them, the Western, has participated in special University privilege, the Royal and Victoria Infirmaries being on the same platform. The governors object to this equality being disturbed, especially when it is largely to be accomplished by money from the Muirhead Trust. So far the Muirhead trustees have not expressed any willingness to assist the Victoria Infirmary equally with the Royal Infirmary, notwithstanding that the governors of the Victoria Infirmary have approached them and asked to be put on a similar footing. The case of the Victoria Infirmary is regarded by the governors as being peculiarly strong in relation to the Muirhead Trust, as Dr. Muirhead in his will expressed as his final opinion and direction that his proposed college "might and should be placed in proximity to the Victoria Hospital." Clearly, therefore, according to them the Victoria Infirmary has a greater claim to participate in the funds left by Dr. Muirhead than any other institution in Glasgow. As showing the opinion formed by competent judges upon the special claims of the Victoria Infirmary the governors point to the fact that the judges of the Court of Session, in sanctioning a permanent constitution for the disposal and application of Dr. Muirhead's bequest, framed a board of representative governors, of whom three were to be appointed by the governors of the Victoria Infirmary, and not by any other infirmary in Glasgow, and not more than two by any other of the great public bodies of Glasgow. The governors of the Victoria Infirmary, therefore, appear to have been surprised to learn that the Muirhead Trust are promoting a provisional order to enable them to pay over annually £800 to the scheme of the Royal Infirmary whilst they have refused in any way to recognise the claims of the Victoria Infirmary. At the meeting last week they accordingly felt that no course was open to them but the legal course of opposing the provisional order, and they unanimously agreed to adopt that course and to enter formal opposition to the provisional order when it should come before the Parliamentary Committee.

A Medical Officer's Salary.

Recently the health committee brought forward at a meeting of the Kirkintilloch town council a recommendation that applications be invited for the post of medical officer of health to succeed the late Dr. Whitelaw, the applicant to have the diploma of Public Health, and the salary to be £30 per annum. It was also moved that the officer be not allowed to practise in the burgh, with a view to his having no private interests to clash with the discharge of his public duties. It was then moved that the salary be £40 per annum, the mover styling it preposterous to offer the sum of £30 to a man of such qualifications as were required; the men who cleaned the council's streets were better paid. On the vote being taken the committee's recommendation was agreed to.

Dundee School Board and its Medical Officer.

Last week at a meeting of the Attendance Committee of the Dundee School Board the question came up of appointing a medical officer. The convener pointed out that it had already been decided to appoint a medical inspector and two nurses. They came now to make arrangements for advertising for such a man as the board might think suitable for the post. The clerk had submitted the scheme which the board had agreed to. The clerk read the reply from the department, which set forth that "My Lords" were in full agreement of the scheme as regards general principles; they, however, regard as a sinc qua non that the inspector should hold a diploma in Public Health, which last provision the chairman held as outside the provisions of the Act, and the clerk stated that on his making inquiries of other boards he found that no such provision was suggested in their cases.

Professor J. A. C. Kynoch.

Professor Kynoch of Dundee University College Medical

School and Dean of the Faculty of Medicine in the University of St. Andrews, has been elected as an honorary Fellow of the Munich Gynæcological Society.

Medical Inspection of School Children in Banffshire.

A conference was held on Nov. 6th on this subject in Keith, between the secondary education committee for the county of Banff and representatives of the various school boards within the county. A subcommittee which had considered the matter submitted the following three schemes:—

1. The appointment of a duly qualified medical practitioner, with a Public Health qualification, who would devote his whole time and perform the whole work at an estimated salary of £450 per annum, being £300 as salary, and £150 for expenses.

2. The appointment of the medical officer of health for the county as medical officer in chief, with a qualified assistant, having a special knowledge of ear, throat, and eye, and the degree of Public Health, if possible at an estimated salary of £500.

3. The appointment of the medical officer of health for the county as medical officer in chief, with the local medical officers of each district as his assistants, at an estimated expenditure of £600, made up as follows: Salary of medical officer £65, expenses £80; salary of local medical practitioners £375, expenses £80.

The vote resulted in scheme No. 3 receiving 18 votes; No. 2, 2 votes; and No. 1, 4 votes. Scheme No. 3 was accordingly adopted, and was ordered to be sent to the secondary education committee with a view to their formulating a scheme in accordance therewith, so that it might thereafter be submitted to school boards in draft for their consideration.

Aberdeen University: The New Principal.

On Nov. 9th a meeting of the Senatus of the Aberdeen University was held, when Dr. George Adam Smith, the newly appointed Principal of the University, presented his commission of appointment. Professor W. Stephenson, the senior professor, presided, and on behalf of his colleagues offered the new Principal a cordial welcome.

Nov. 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Sir Charles A. Cameron.

THE veteran Dublin sanitarian, Sir Charles Alexander Cameron, has been presented with an illuminated diploma honorary membership of the Irish Central Veterinary Association. A special dinner was given at the Gresham Hotel for the purpose of carrying out the ceremony of presentation under the presidency of Mr. P. J. Howard, M.R.C.V.S., who reminded his audience that their association represented veterinary practitioners of every part of Ireland, and that they had decided on paying Sir Charles Cameron the present compliment in recognition of the fact that he had invariably proved himself the staunch friend of their profession. He it was who fought for the object of having a whole-time veterinary officer appointed to the Public Health Department in Dublin, and eventually succeeded in having Mr. Watson chosen to that post. At the various congresses of public health and at the sanitary institutes he had at all times shown himself to be the friend of the veterinary profession. The text of the diploma was then read by Mr. Watson, after which the health of the recipient was drunk with great enthusiasm and musical honours. In his reply, Sir Charles Cameron expressed a deep feeling of gratitude for the compliment paid to him by the leaders of a profession other than his own, which he had always regarded as a sister profession, and one which he thought possessed the strongest claim to stand upon a very high level-adding that to a great extent the education of the veterinary physician and that of the physician for mankind were carried out on the same lines. He was proud on being reminded a few days before of an early effort of his to establish a veterinary school, and also of the fact that they have now so very successful a Veterinary College in Ireland. After a few appropriate remarks from Professor Mettam (President of the College), Dr. M. F. Cox (senior physician to St. Vincent's Hospital) paid a high tribute to the attainments of the veterinary profession in this country, and expressed the belief that "the health of all our towns would be much improved if the veterinary surgeons were better recognised."

Irish Forestry: Celebration of "Arbor Day."

The "sloblands" at Fairview (near Clontarf), furnished the text for so much discussion during last year's epidemic of enteric fever in the vicinity, are being filled in with a rapidity which promises to establish a record in the annals of Irish industry. A wealthy resident Clontarf proprietor generously presented a number of shrubs and trees which were planted there on Nov. 6th. Last year, indeed, "Arbor Day" was similarly celebrated in the same enclosure on a smaller scale, and the promising growth which resulted has undoubtedly enlisted many enthusiastic recruits. The work of planting was carried out according to the method recommended by the Irish Forestry Society, which progresses daily in its activities. Another manifestation of this fact has just been displayed in Limerick, the corporation of which has decided on the purchase of 200 trees and the planting of the same in selected localities in the various wards of the city. And Arbor Day has also been celebrated in Bray under auspicious conditions, for the first instalment of tree-planting was carried out by their Excellencies the Earl and Counters of Aberdeen.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Payment of Gratuities or Commission for Recommending Patients.

In a circular directed to all the Aerzte-Kammern (Medical Councils) in Austria, the Aerzte-Kammer representing Styria has called the attention of the profession to a discreditable system which has attained considerable proportions within the last few years, and which tends to lower the position of practitioners in the eyes of the public. What the circular chiefly complains of is that in many places it has become customary for the proprietors of sanatoriums, hydrotherapeutic establishments, convalescent homes, and other similar institutions to pay commissions to the medical men who send patients there for treatment. It has also happened that specialists have been forced in several instances to hand over to the patient's ordinary medical attendant from 20 to 50 per cent. of the fees which they (the specialists) have received for performing an operation; and instances are known where porters, hotel servants, nurses, and midwives have been bribed by substantial percentages of the fees paid for medical advice by patients who were brought or introduced The honourable members of the profession by these people. can only protest against such abuses, because the acts in question are not illegal, and the Medical Councils have no power to punish their members who do not conform to ethical conventions. A reaction has, however, now set in, originating with the proprietors of sanatoriums and similar institutions, who are endeavouring to combine for the purpose of resisting demands for the payment of commission. At the same time the Aerzte-Kammern are explaining matters to their members to enable them to boycott those practitioners who try to get commissions from the consultants and specialists recommended by them. The public themselves have become suspicious and go to a specialist without first informing their family adviser, often even telling the specialist that they have no regular medical attendant. Naturally this tends to diminish the confidence which ought to exist between the patient and the practitioner, and is objectionable in various ways. The suggestion of the Council of Styria is to call a meeting of medical representatives, who would endeavour to find some means of correcting this evil, which, as it has now grown strong, will be difficult to eradicate. It must be kept in mind that the cost of living has become dearer in this country by at least 40 per cent. within the last 18 years, and that the majority of practitioners here come from families not overburdened with wealth.

Horseshoe Kidney.

At a recent meeting of the Gesellschaft der Aerzte Dr. Paschkis showed three preparations of portions of horseshoe kidney, a condition which is not very rare and is always very unpleasant to the surgeon who may encounter it in the course of an operation. In the first case the patient was a man 57 years of age who had been suffering for 10 years from difficulties in micturition. Examination by the X rays

revealed the presence of concretions in the right kidney and the urine from the right side was purulent, while that from the left side was clear. Pains of a colicky nature were frequent, and Professor Zuckerkandl therefore performed an operation during which it was discovered that whilst the upper extremity of the right kidney was easily freed from the adjacent structures the lower extremity was connected with the left kidney by a bridge of renal tissue extending across the vertebral column, the case being in fact one of horseshoe kidney, in the right part of which calculi were lodged. This right half was resected in front of the vertebral column, with the accompaniment of severe hæmorrhage from abnormal and atypical vessels. The patient made a good recovery and at present feels quite well. The second patient had been suffering from profuse intermittent renal hæmorrhage, which by repeated separations of the urine was ultimately found to come from the right kidney. An operation was considered to be inadvisable, as purulent urine containing casts came from the left kidney, but the patient was very anxious to have one performed, preferring the risk to his constant debilitating hæmorrhages. The X rays gave no clue to the diagnosis, and a neoplasm was suspected. When an operation was at length undertaken pyonephrosis of the right half of a horseshoe kidney was found, numerous concretions being present. The resection was successful and the patient made a good recovery from it, but died two months after the operation from chronic bronchitis. Necropsy verified the diagnosis of horseshoe kidney. The third patient was a woman with an undefinable tumour of the abdomen. Laparotomy showed cystic degeneration of the right half of a horseshoe kidney. Conservative treatment was adopted here. Dr. Paschkis said that the diagnosis of such cases was very difficult before operation; in fact, hardly ever The operation itself was extremely difficult, although the results were not unfavourable. Great care should be taken not to resect a kidney unless both its extremities have been found and freed from their connexions so as to diminish the risk of complications.

The Water-supply of Vienna.

At this time last year there was a serious water famine in Vienna owing to the drought which had continued since the previous July and the absence of all snowfall later. This year, however, there is an abundance of good water, which has been brought to the city by the new waterworks. There are at present two large systems of waterworks in construction besides the two existing ones, and these will be completed in 1911, so that then there will be at disposal a quantity of 2,500,000 hectolitres daily, or more than 1 hectolitre (25 gallons) per head of the population. Last year, before the second series of waterworks was ready, the amount was less than half of that even in times of full supply, but now, even in the event of shortage, a quantity of at least 1,400,000 hectolitres will be available every day, sufficient for all purposes. The water comes from the Schneeberg (6000 feet high) and the Otcher mountains (6300 feet high), a distance of 80 miles, whilst the new waterworks bring the water from a distance of 116 miles to the city. It is a clear hard water, with a constant temperature of 6-7° O. in winter and 7-9° in summer, containing hardly any organic matter, and with a moderate degree of hardness, leaving a small calcareous deposit on boiling. Ever since the first series of waterworks commenced to be used in 1873 typhoid fever has hardly been met with in this city, whereas formerly it was constantly present. The increased incidence of "strumous" disorders has been ascribed by many authorities to the bringing of this water from mountain districts into the city, but this hypothesis has not yet been proved. However that may be, the new water-supply is so abundant and pure that Vienna stands in this respect an easy first amongst all large cities.

Nov. 13th.

SMALL-POX IN LONDON.—Since Oct. 28th four cases of small-pox have been notified in the county of London. All of them have occurred in Stepney and the London County Council has brought the matter to the notice of the Whitechapel board of guardians, expressing the hope that the board will arrange for the vaccination or revaccination of all persons who may be specially exposed to the danger of infection.

Ghituary.

HENRY HUGH CLUTTON, M.A., M.C. CANTAB., F.R.C.S. Eng.,

SENIOR SURGEON TO ST. THOMAS'S HOSPITAL, LONDON.

In Henry Hugh Clutton, whose death occurred on Nov. 9th, at the age of 59 years, the profession has lost one of its most able, energetic, and distinguished surgeons. His last illness was a long and very painful one, and was borne with remarkable fortitude. It began in the summer of 1908, and, although some alleviation followed an operation performed at that time, the symptoms recurred with increased severity in July last. From that time until the very end he met all his troubles with courage beyond all praise, displaying throughout a determination to get well, if that end could by any means be accomplished. His heart was so deeply in his work that he longed to get back to it, and he expressed, even shortly before his death, his keen desire to return to his hospital duties next January.

He was born in 1850 at Saffron Walden, where his father was for many years vicar. He was sent to school at Mariborough, but had to leave prematurely owing to ill-health, from which he suffered for some years after. Subsequently he went to Clare College, Cambridge, and, after leaving the University, entered as a student at St. Thomas's Hospital in 1872. There he had a distinguished career, and was appointed resident assistant surgeon in 1876, later assistant surgeon, and finally, in 1892, full surgeon. At the time of his death he occupied the position of senior surgeon. As a member of the staff of an important hospital he created for himself a reputation which will long persist both in his own school and far beyond its walls. A man of strong character and lofty aims, he exercised an influence on all with whom he came in contact, whether pupils, colleagues, or patients, and few men have possessed more capacity of actively interesting themselves in the affairs of others or acquired a more devoted following. Clutton enjoyed the privilege of living actively during the most striking and rapid era of advance in the science and practice of surgery that the world has known, and in the labours of this advance he bore a yeoman's share, one of the strongest features of his work being his capacity to assimilate and utilise the progressive facts afforded by the growing science of pathology, and readily to abandon beliefs and methods on which he had depended as soon as they proved untenal·le or capable of improvement. The single word "thoroughness" suffices to describe the character of his work; a general surgeon in the best sense of the term, he was able to take an equal interest in whatever class of case might come before him, and a glance at the titles of the long list of papers written by him shows how wide a field he traversed. Mention of a few only of the subjects which especially attracted his attention is compatible with the length of this notice.

At the commencement of his career, whilst surgeon in charge of the department for diseases of the ear, he was an early advocate of an active attitude in the treatment of suppuration of the middle-ear and its annexes, a department of surgery which has since acquired so great importance. To this period of his life we owe also the urethral sounds associated with his name. In abdominal surgery his early successful operations for intestinal obstruction due to a persistent Meckel's diverticulum and to an impacted gallstone, the treatment of the dilated sigmoid colon by anastomosis and removal of the loop, and the removal of a pancreatic cyst may be cited, while the paper on the treatment of appendicitis, published in the St. Thomas's Hospital Reports for 1897, might be republished at the present day. Diseases of the bones attracted much of his attention; he was an early advocate of limited removal in the case of myeloid sarcoma; he wrote on late rickets, completing an account of his observations during the term of his presidency of the Clinical Society of London; and contributed the article on this subject to Treves's "System of Surgery." Another department of surgery in which he excelled was that of orthopædics, his splendid results in this field being due to the energy and perseverance he displayed in treating hi cases to the end.

Clutton was not an originator of methods, but he stamped

Henry Hugh Clutton, M.A., M.C. Cantab., F.R.C.S. Eng , senior surgeon to st. thomas's hospital.

those he adopted with an individuality of his own. mencing as an ardent disciple of the antiseptic faith, he became a strong and early supporter of aseptic methods, and in his precision as to details, especially in the care with which handling of the wound and its tissues was concerned, he was second to no man. As an operating surgeon, boldness, combined with excellent judgment, were his main characteristics. He rarely operated on any case, except in an emergency, without devoting an unusual amount of thought and consideration to it; each patient's disease formed a problem for his mind which he worked out to the very best of his capacity before proceeding to attack it, with the result that he was comparatively rarely confronted with a position for which he was wholly unprepared. Again, the after-results of his operations were followed with an enthusiasm equal to that with which the methods of treatment had been undertaken. Clutton was a wide reader, but the value of his contributions to surgical literature depends upon the fact that they are founded entirely on his own observation, and hence form reliable and practical aids to those who consult them. It is difficult to ascertain their exact number, but he contributed some 25 communications to the Transactions of the Pathological Society, 19 to those of the Clinical Society, 3 to those of the Royal Medical and Chirurgical Society, 17 to the St. Thomas's Hospital Reports, in addition to numerous contributions to the medical press, the Annals of Surgery, and the American Journal of the Medical Sciences. He also wrote, as has been said, the articles on Diseases of the Bones and Deformities for Treves's "System of Surgery, article on Pyæmia and Septicæmia in Holmes's "System," and made a translation of von Esmarch's "Handbook for Military Surgeons." As a teacher he belonged to the school who regard the study of pathology as the proper preparation for a successful surgical career, and he perhaps somewhat unduly underrated the old-time course by way of the anatomical department. His lectures were popular and well attended, but his strong point was as a clinical teacher; he always attracted a large class both of the junior and more advanced students, and, as was the case with his writing, the feature of his clinical teaching was that the instruction was the direct outcome of practical personal experience. During the whole period of his professional life he kept careful notes in his own hand of every case of importance in his practice, whether private or in hospital, while these histories were kept up for years after the patients left his charge. A considerable time daily was devoted to this work, by means of which he accumulated an enormous and exact practical experience, and it is sad to think that physical weakness, steadily borne up against, and the catholic nature of his occupations prevented his making a great deal more use of the material in his possession than he was able.

Clutton was very highly respected by his colleagues on the Council of the Royal College of Surgeons of England, where he was nearing the completion of a first term of office. At first a little impatient with the dignified and deliberate methods of procedure, which were ill-suited to his constitutional desire for rapid action, he became gradually and increasingly interested in the work of the College. He did much valuable work in committees, where he often shone more than in the formal procedure of a larger body. He was very much interested in all matters connected with the medical curriculum, and of late was much occupied with the question of more fully utilising the material of the Hunterian Museum for the purpose of teaching pathology.

This brief notice of the surgical aspect of Clutton's career cannot be concluded without emphasising the value of the work he performed for his own school. Beyond the information he imparted, his strenuous example reacted upon his colleagues and pupils and influenced them deeply. His colleagues will sadly miss his stirring spirit from amongst themselves, while many a man will feel that he has lost a friend ever ready to be consulted and to give valuable and practical advice.

We are indebted to Dr. S. J. Sharkey for the following personal appreciation:—"The writer first made the acquaintance of Clutton in 1876, when he held the post of resident assistant surgeon, and from that time till his death he remained on terms of the closest intimacy and friendship with him, and acted as his medical colleague during the whole period of his full surgeoncy. Clutton possessed in a

very high degree the scientific mind. He was a patient, careful, and skilled observer; no trouble was too great for him, whether it was required in the pursuit of purely scientific knowledge or in sifting the signs and symptoms at the bedside. Throughout his career he was a keen pathologist, and his whole knowledge and art of surgery was founded on the pathology of the day, of which he kept himself well abreast. His intellect was keen and powerful, and the reasoning power he displayed in forming and explaining the conclusions he arrived at was of the highest order. His surgery was from beginning to end rational. The love he had for his work was palpable to all, and the interest he took in his patients was not limited to their diseases, but embraced their whole welfare. He had a great love for children, and when he came to see them professionally his first thought appeared to be to play with them, and this he generally did. His value as a colleague in the wards of the hospital cannot be over-estimated. Once called in consultation, he would come again and again of his own accord to watch the case until he had come to a final conclusion as to what was the best course to pursue. In this way one's responsibility in the care of serious and urgent cases was equally shared with him, and the burden of them greatly lightened. Clutton's endurance and capacity for work were very remarkable in his early days; indeed, until about the last 12 years of his life he seemed never to tire, but to work all day and read and write until late at night. His strength was first sapped by two serious illnesses due to septicæmia from poisoned wounds about 12 years before his death. He was left by them in a condition of profound neurasthenia, and yet with an indomitable determination to work. Nothing proved what force of character he possessed more than the manner in which he carried on both hospital and private work under difficulties which would have paralysed most people, and this for years. In fact, he never was the same man again. He used to do an ordinary full day's work, although it exhausted him to walk even to the top of Portland-place and back; and on his return from the hospital he frequently had to remain lying on his back unable to do anything for the rest of the evening. business of Clutton's life was not, however, confined to his hospital and private practice. His interest and work extended in many directions, and he took upon himself gladly many public duties. His business capacity and readiness to serve on all kinds of committees concerned with the general management of his hospital and school caused a great addition to his life's work, and deserves to be remembered with gratitude by those to whom he so gladly gave his time. His activities extended, however, far beyond the walls of St. Thomas's. He was a visitor for many years to King Edward's Hospital Fund; he represented the Royal College of Surgeons of England on the Senate of the London University and on the executive committee of the Cancer Research Fund. He was consulting surgeon to Osborne; treasurer of the Medical Sickness, Annuity, and Life Assurance Society and of the Convalescent Homes Association. He was also at one time surgeon to the Victoria Hospital for Children, and he was the last President of the

Clinical Society.

In any notice of Clutton's career, however cursory, his relations with medical students deserve special mention. He was a clear and admirable teacher at the bedside, and he took special pleasure and pride in the classes he held in the wards for this purpose. He was always followed by a keen and appreciative crowd of students, numbers of whom, but perhaps especially the more advanced men, derived the greatest advantage from his brilliantly clear and practical instruction. In one respect Clutton richly deserves the title of 'students' friend,' when one thinks of the number of them who are to be found, not only in this country but in many others, who have profited by his knowledge of the world, and of the conditions of general practice. Just at the time when they became qualified, and were uncertain what to do, or how to do it, Clutton was always at their service, and would consider each one's case and prospects with the utmost interest, and give them the soundest and most business-Many a man, I have no doubt, would like advice. be only to ready to acknowledge how deep his debt is to Clutton for past kindness and wise advice. As regards general character, Clutton was as straightforward abhorred everything that savoured in the slightest degree of humbug. He held strong views and defended them with vigour. He had a great dislike, however, of squabbles or heated discussions, though he would not flinch from them if they were forced upon him. He did not like publicity or parade of any kind, and avoided them when possible. He was a very generous man, but his wisdom and common-sense ensured that his generosity was bestowed upon worthy objects. He loved sociability and hospitality, but not that of the grand type; he preferred the unpretentious meetings of a small number of friends as often as opportunity arose.

During the last 12 years of his life his physical capacities were of a very restricted order, and he could not indulge in active exercise. But in earlier days we used to go for walking expeditions in the Lake District, Scotland, and elsewhere, and in these he took great pleasure. Though never given to fishing in his youth, he was later on seduced, and we spent our holidays together on more than one occasion on Scottish and Irish lakes and rivers. Clutton was a great reader, and was particularly fond of works on history, art, architecture, and travel. To visit celebrated picture galleries and the best specimens of ecclesiastical architecture always gave him keen pleasure. I think it can be truly said that the happiest period of his life was his married life, notwithstanding the fact that it was marred by so much ill-health; for he married a wife who was as devoted to him as he was to her, who became his constant companion, and helped him in his correspondence and work as in many other ways, and who satisfied his love for children by giving him a little daughter who was the joy of his life, and who stood by him in his last illness with the most unflinching devotion.

Clutton, alas! is gone, and prematurely; but it may in truth be said of him that though dead he yet speaketh and will continue for many a day to speak in the hearts and lives of many old friends and pupils now scattered over the face of the earth."

SIR WILLIAM THOMSON, M.A., M.D., M.CH. R.U.I., F.R.C.S. IREL., C.B.,

HONORARY SURGEON TO H.M. THE KING; LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND; SENIOR SURGEON TO THE RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, ETC.

THE death of Sir William Thomson, which took place at his residence, 54, St. Stephen's Green East, Dublin, on Nov. 13th, has deprived our profession of one of its most prominent and trusted members, and leaves a sensible blank in the surgical and social life of the Irish metropolis. Descended from mixed Scottish and Irish stock, William Thomson was born in Downpatrick on June 29th, 1843. He was the youngest son of William Thomson of Lanark, a member of a leading Scottish family. His mother, who was of Irish birth, was also of remote Scottish descent. His father died while the future surgeon was still young, and in time his mother married Mr. McDougall, the proprietor of the Galway Express, an arrangement which determined the residence of young William Thomson in the western capital of Galway, and his education in the Queen's College (of the Queen's University) of that city. It was at that institution that he first distinguished himself as a student, and gave indications of the early development of high qualities, both moral and intellectual. His continuous and unwearied industry during his undergraduate course furnished ample proof of the grit and devotion to the call of duty which distinguished him throughout his whole career, while his success as a student showed his various teachers that they were engaged in the furnishing of a mind of peculiar parts and powers, having a flexibility which disarmed opposition and emulous detraction. This quality accompanied him all through life, and was one of the many for which he was so often held up as a model for the imitation of juniors in any of the various walks of public life. He repeatedly distinguished himself by capturing the principal prizes open to the competition of his class, including the distinction of a scholarship of the University, and graduated in Arts in the year 1867.

At this stage in his career he took a position on the staff of the Daily Express. The journalistic training thus received was of great use to him, giving him the power of quick discrimination in matters literary and scientific between the wheat and the chaff. Moreover, in a

country like unrestful Ireland, where politics have ever influenced all other callings, the journalistic training was especially useful. "It is probably difficult," Irish correspondent to us upon this very point, "for anyone who has not lived behind the professional scenes in Ireland to realise what the full significance was of so important an agency as that of Sir William Thomson in the tortuous pilgrimage of evolution of political liberty and intellectual enlightenment through which this country has been passing during the whole period of his active professional life. But those who have had the privilege of being so placed know best, and deplore most, the fact of the bereavement which best, and deplore most, the fact of the bereavement which the Irish public in general, and the surgical section of the same in particular, have just suffered by the removal from amongst us of Sir William Thomson. His many contributions to the literature of his profession bear the unmistakeable stamp of his journalistic training: in the critically judicious selection of material to start with; in the descriptive and discursive powers displayed; and in the generally esthetic, as well as judicious, arrangement of

His professional career began in 1872, when he graduated as M.D. and Ch.M. of the Queen's University, Ireland. Increasing appreciation within his own profession and recognition by the public followed, for he had dignity of presence and charm of manner and address to help him as well as an obviously high sense of professional duty. He at once obtained the positions of house surgeon to the Richmond Hospital and demonstrator of anatomy to the "Carmichael (Richmond Hospital) School of Medicine, in which school he was in the course of the following year appointed to the post of lecturer on anatomy. Utilising, as he did, every opportunity of increasing general and professional knowledge his anatomical and other attainments secured him the election to an examinership in anatomy and surgery in the Royal College of Surgeons in Ireland in 1875. He had been promoted to the visiting staff of the Richmond Hospital in 1873, and obtained by examination the Fellowship of the Royal College of Surgeous in Ireland in 1874. This examinership in anatomy and surgery was held by Thomson till the want of much-needed reform, in the genesis and advance of which he took so active and so judicious a leading part, remodelled the curriculum and the examinations for the diploma of the Royal College of Surgeons, and ultimately led to the inauguration of the present "Conjoint scheme of union with the Royal College of Physicians in the issue of the double diploma. Few members of the profession in Ireland played so comprehensive a rôle in the reformation of the Irish school of medicine and surgery, which was carried out in the last couple of decades of the last century, but it must be said that in the whole of this movement he had the support of Mr. (now Sir Thornley) Stoker, Mr. Corley, then the leading spirit of the Carmichael Medical School and Thomson's old master, and Dr. G. H. Kidd, who was then a great motive force in the Council of the Royal College of Surgeons. Thomson became secretary to the Court of Examiners under the new scheme, but his active interest in, and attachment to, his own University never slackened during the course of all this important work, and he was appointed examiner in surgery at Galway in 1879, and received its degree of M.A. (honoris causa) in 1881. On the merging of the Queen's University into the "Royal" he was elected a Representative of Convocation in the Senate.

Thomson's literary proclivities were proved by his obtaining, as an undergraduate, the prize offered by his university for an essay on "The Outbreak of Yellow Fever at Buenos Ayres." In 1877—then a junior surgeon on the visiting staff of the Richmond Hospital—his combined surgical and literary reputation secured the confidence of Stokes, consulting surgeon of that institution, who employed him to edit his volume on "Injuries and Diseases of the Genito-urinary Organs"; and of the publishers of "Power's Surgical Anatomy of the Arteries," who procured his services as editor. In 1882 he ligatured the innominate artery, an operation which was survived by the patient for a time considerably above the average record, and he wrote soon after a very comprehensive monograph on "Ligature of the Innominate Artery." His surgical reputation was now thoroughly established, and he was in demand in all parts of the country, but he still found time for work in constructive medical politics as is shown by his connexion with the Royal Academy of Medicine

in Ireland. Towards the close of the year 1882 the several medical societies in Dublin, which had for some years been dragging out a failing existence, had agreed to amalgamate in the constitution of a complex body bearing the name Academy. There was the inevitable discussion and controversy before the new institution was definitely constructed. Thomson's well-known ability in this direction—and adaptability in almost every other—led to his unanimous choice as secretary, and in no sphere of his varied professional lines of activity were his qualities shown to greater advantage. "Thomson's presence," writes a correspondent, "has been during the past 30 years one of the most potent factors in the leavening of the professional public life of Dublin—with its vast over-supply of professional institutions and of professional men (and women). And his influence has invariably been of the very best. His lofty principles and ideas of duty and its calls carried him through troubled voyages of professional circumstances which would, most assuredly, have worn out the enthusiasm of most. And his bearings to his contemporaries and fellows in every walk of life were equally praiseworthy."

The rest of his career may be briefly summed up, for it is public property and has already been sufficiently dwelt upon in many newspapers. From 1896 to 1898 he was President of the Royal College of Surgeons in Ireland, receiving the honour of knighthood in recognition of his professional position. Sir William Thomson's presence was missed in Dublin during a certain period of the Boer war, when he went to Africa as head of the Ambulance Corps which was despatched "to the front" by the munificent gift of Lord Iveagh. He was accompanied in this expedition by his brother-in-law, Mr. George Stoker, and their active and harmonious efforts contributed to the relief of innumerable sufferers in that period of trial. He later received the decoration of C.B. in 1900.

Sir William Thomson married Margaret Dalrymple, second daughter of the late Abraham Stoker of Dublin and sister of Sir Thornley Stoker, by whom he leaves a daughter and a son, who is a member of the medical profession.

WILLIAM ANDREW HAYES, L.R.C.P. LOND., M.R.C S. Eng.

Mr. W. A. Hayes died recently at his residence in Mafeking, South Africa. Mr. Hayes, who studied at University College Hospital, London, qualified L. R. C. P. and M. R. C. S. in 1892. He shortly afterwards commenced practice at Calne, Wiltshire, and remained there until about 1895, when owing to threatened lung trouble he went to Mafeking. Mr. Hayes was at one time attached to General Baden-Powell's force, during the greater part of the siege of Mafeking he was principal medical officer to the garrison, and later was surgeon-lieutenant of the Bechuanaland Rifles. Mr. Hayes was very popular in Mafeking, and the Mafeking Mail, in recording his death, said that he "gained the esteem of all by his geniality and good-heartedness." Mr. Hayes was also respected by the natives, as shown by the following notice in the same newspaper: "Chief Lekoko, on behalf of himself and the Baralong nation, desires to convey to Mrs. Hayes and relatives of the late Dr. W. A. Hayes their heartfelt sympathy."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical man are announced:—Dr. Matthael of Berlin, an eminent temperance advocate, has been killed at Tübingen in a motor-car accident. His age was 58 years.—Dr. John J. Quirk, assistant professor of dermatology in the Chicago College of Physicians and Surgeons.—Dr. Richard Wehmer, medical referee to the Berlin police, has died from heart disease while on a motor tour at the age of 54 years. He was assistant to several Leipsic professors and became an expert otologist and gynæcologist. He practised for several years in Frankfort, his native town, coming in an official position to Berlin in 1887. He afterwards obtained an appointment under the Rhenish Medical Collegium in Coblentz and three years ago returned to Berlin as successor to Dr. Wernich. He was a somewhat voluminous author on hygienic subjects and was President of the German Society of Public Sanitation.—Dr. Alois Monti, extraordinary professor of children's diseases in the University of Vienna, at the age of 70 years. He was

for many years assistant to Professor Widerhofer, and in 1893 was appointed director of the General Polyclinic. He published an important series of monographs in 28 parts on Children's Diseases and their Treatment.—Dr. John P. Reynolds, formerly professor of midwifery in Harvard University.—Dr. A. V. Natanson, privat-docent of ophthalmology in the University of Moscow.—Dr. Martini, who was for many years senior medical officer of the Dresden City Hospital. He was 80 years of age.

Medical Rews.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians on Oct. 28th, and at a meeting of the Council of the Royal College of Surgeons on Nov. 11th, diplomas of L.R.O.P. and M.R.C.S. were respectively conferred upon the following gentlemen who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Examining Board, and have complied with the necessary by laws:—

Assed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Examining Board, and have complied with the necessary by-laws:—

JOHNSON v. KENDALL AND THE BRIXTON FREE PRESS: RETRACTATION AND APOLOGY.—In the issue of the Normood Observer for July 4th, 1908, certain statements were published concerning Dr. Alice Vowe Johnson, medical officer to the out Poor-law schools at Norwood, attributing to Dr. A. V. Johnson autocratic behaviour, incompetence, and negligence. The Medical Defence Union took up the lady's case with the result that a complete retractation of all the charges has been made by the defendant printing and advertising company, who submitted to judgment against them with costs as between solicitor and client, as well as to publication in the press of a formal retractation and apology. We congratulate Dr. A. V. Johnson on the determination to face a possibly disagreeable ordeal in the cause of justice, and note, once again, the value to members of the medical profession of belonging to a defence

PRESENTATION TO A MEDICAL MAN.—Mr. Randal Herley, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., house surgeon at Dewsbury and District General Infirmary, was at the monthly meeting of the infirmary board held on Nov. 9th presented with a case of eye instruments from the honorary medical staff, a field-glass from the matron and nurses, a fountain pen from the secretary, and a gladstone bag from the cook and maids. Major Walker, the president of the infirmary board, who made the presentation, expressed his regret that Mr. Herley was leaving the institution which he had served so well for four years. He had endeared himself to all who knew him, and especially to the poor of the neighbourhood. Mr. H. Fitton, honorary surgeon to the infirmary, fully endorsed the remarks of Major Walker, adding that the institution had never been better served by any house surgeon.

CHILDREN'S CARE ASSOCIATION FOR WEST SUSSEX. -At a conference arranged by the West Sussex and Chichester joint education committee at Worthing on Nov. 13th it was unanimously resolved to form a Children's Care Association for the western half of the county to follow up and remedy the cases reported on by the school medical officer as requiring attention. The Duchess of Norfolk has accepted the presidency of the association. It is proposed to work directly with the education authorities, inasmuch as the education committee is to be asked to consider and suggest a scheme for consideration by the association. The chairman of the West Sus-ex education committee, Mr. W. E. Hubbard, who presided at the conference, said that the first object of the working members would be by personal intercourse with the parents to show them what to do and to persuade them to do it. Pecuniary assistance would not be sought until the parents had done what they could, and public money would not be spent except in special cases where it was beyond the power of the parent and of any available voluntary effort to provide the means to cure. The aim was to institute a voluntary agency

without imposing on the local medical men or on the managers of hospitals.

University College Hospital Medical Society. -The annual dinner of this society will be held on Nov. 26th at 7.30 P.M. at the Gaiety Restaurant, Strand.

Mr. Ernest Dykes Bower, M.D. Durh., F.R.O.S. Edin., M.R.C.S. Eng., L.S.A., has been unanimously elected Sheriff of Gloucester.

According to the Times' New York correspondent, a Radium Institute for America has been organised in that city under the presidency of Dr. Chandler, professor of chemistry at Columbia University.

The Metropolitan Hospital has been reopened for the reception of patients after four months renovation and in part reconstruction. The improvements have been carried out at a cost of £10,000, towards which sum the committee is appealing for funds.

MEDICAL MAGISTRATES.—The name of Mr. Sack Noy Scott, L.R.C.P. Lond., M.R.C S. Eng., D.P.H., medical officer of health of Plympton-St.-Mary rural district, has been placed on the commission of the peace for the county of Devon.—Mr. H. O. Hughes, L.R.C.P., L.R.C.S. Edin., has been placed on the commission of the peace for the county of Denbigh.

MUNICIPAL HONOURS FOR MEDICAL MEN.—Mr. Colston Wintle, L.R.C.P. Lond., M.R.C.S. Eng., who for the past 12 years has been a member of the Bristol city council and for six years chairman of the health committee, was re-elected by a large majority as the representative of the Horfield Ward.—Mr. Richard James Herbert Scott, F.R.C.S. Edin., consulting surgeon to the Royal United Hospital, Bath, was elected a member of the Bath town council.—Mr. Henry Edward Waddy, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H. Camb., was unanimously re-elected chairman of the Gloucester Education Committee.

LONDON AND COUNTIES MEDICAL PROTECTION Society, Limited.—A special general meeting of the members of this society will be held on Wednesday, Nov. 24th, at 4 o'clock, at 31, Craven-street, Strand, W.C., for the purposes of considering, and, if thought fit, passing, with or without modification, a resolution to the following effect, viz. :-

To approve the action of the Council in arranging for an insurance of the members of the society against any damages or costs up to several thousand pounds which may be awarded at any time against any member in any proceedings which the society may undertake on behalf of its members pursuant to Article 16 of the Articles of Association of the Society, and for that purpose to raise the subscription of the members of the society to a sum not exceeding £1 per annum.

A large number of the members of the society have already effected individual insurance against damages and costs in defensive actions only, and it is now thought desirable to insure the whole of the members of the society collectively. The insurance can be effected much more satisfactorily when the society is insured en bloc, and if the above scheme is carried through a member of the society will be indemnified against any loss, whether he succeeds or fails in any action, provided only that his case is undertaken by the council of the society.

POTTERY EXHIBITION. -LEADLESS Nov. 23rd, 24th, and 25th there will be held in the large Caxton Hall an exhibition of leadless-glazed china and earthenware. The object of this exhibition is to popularise further the use of ware manufactured without risk to the worker, and thus at once to encourage experiment in leadless glazes and to diminish the occurrence of lead-poisoning among those employed in potteries. The exhibition will be organised on the same lines as the exhibition held at Church House three years ago, but on a much larger scale. A great variety of patterns will be on view, and the exhibits will include pottery adapted to every kind of use, ranging from the ordinary pie-dish to the finely designed and coloured ornamental vase. Some of the stalls will show how all the requirements of a modern house in respect of china and earthenware can be met in leadless glaze. H.R.H. the Princess of Wales is a patroness of the exhibition, and the large and representative general committee includes, among many others, the names of the

Archbishops of Canterbury and Westminster and the Bishops of London and Birmingham. On each day of the exhibition the Caxton Hall will be open from 11.30 A.M. to 10 P.M., reduced prices of admission being charged after 6 o'clock to permit the attendance of working people. Popular lectures on the object of the exhibition by well-known speakers have been arranged for the three evenings.

Hotes, Short Comments, and Answers to Correspondents.

THE PREVENTION OF SPITTING IN THE STREETS.

A CORRESPONDENT has written to ask us whether any regulations exist to prevent spitting in streets and public places. There is no difficulty in obtaining by-laws relative to spitting in closed places, such as institutions, in railway carriages, or in tramcars, and notices prohibiting such a practice may be found in numerous places in many parts of the country. The London County Council has a by-law to this effect. But streets and open spaces have, we believe, been regarded as coming within an entirely different category, and clearly the same objections cannot be raised against the practice in the open as can be urged against it in confined localities. Apart from the question of health, the practice is an objectionable one, and there would be advantage in its control, especially in public places such as promenades and the like. We are under the impression, indeed, that by-laws prohibiting spitting in promenade shelters or in the neigh-bourhood of seats upon promenades have already been sanctioned in certain places either by the Local Government Board or the Home Office. In 1903 the London County Council approached the Secretary of State for the Home Department with a view to extending its by-laws so as to prohibit spitting on pavements and footways. The Secretary of State, however, stated that he would not be prepared to allow the extension as there were not the same grounds for prohibiting the practice of spitting in the streets as existed in the case of public carriages, waiting rooms, and similar closed places. In Manchester and in other towns notices as regards spitting are exhibited in factories and workshops, as well as in common lodginghouses and public houses, and copies of these could no doubt be obtained from the Town Hall, Manchester. We believe that in America heavy fines have been inflicted up in persons who persisted in the objectionable habit of expectorating in public places, and in that country the question has been carried further, and in New York it is enacted that "spltting upon the sidewalk of any public street, avenue, park, public square, or place in the City of New York. or upon the floor of any hall in any tenement house which is used in common by the tenants thereof, or upon the floor of any hall or office in any hotel or lodging house which is used in common by the guests thereof, or upon the floor of any theatre, store, factory, or of any building which is used in common by the public, or upon the floor of any ferry-boat, railroad-car, or other public conveyance, or upon the floor of any ferry-house, depot, or station, or upon the station, platform, or stairs of any elevated railroad, or other common carrier, or into the street from the cars, stairs, or platforms of the elevated railroads is hereby forbidden." This by-law is a section in the "Sanitary Code of the Board of Health of the Department of Health of the City of New York.

TWO WARNINGS.

To the Editor of THE LANCET.

SIR.—A person representing himself to be a partner in a firm of wholesale druggists carrying on business at 9, Mincing-lane, E.C., has recently been calling on members of the medical profession with the object of selling a mineral water of which his firm are said to be sole consignees. This person represents himself to be the father of an assistant physician of one of the London hospitals, and by this representation (which is entirely untrue) endeavours to interest the medical profession in his article. We write on behalf of our client, whose name we give you in confidence, to ask you if you will be good enough to give publicity to the denial of this representation, which is injurious both to our client and his father.

We are, Sir, your obedient servants,

RADFORD AND FRANKLAND.

27, Chancery-lane, W.C., Nov. 15th, 1909.

Messrs. Wilcox, Jozeau, and Co., chemists, 49, Haymarket, S.W., desire to warn members of the medical profession against a man, thinly built, apparently about 40 years of age, shabbily dressed, with a pronounced habit of sniffing, who has been representing himself as their agent, and making extraordinary proposals. No such person 1: in their employ or has had any authority whatsoever to use their

HEALTH MATTERS IN GOLD COAST COLONY: EPIDEMIC OF PLAGUE.

THE Acting-Colonial Secretary (Mr. C. Riby Williams, C.M.G.), reporting on the Gold Coast Blue-Book for 1908, estimates the present population of the colony (including Ashanti and the Northern Territories) at about 2,700,000. The European population is returned at 1768. The health of European residents was not as good as in the previous year, there being an increased death and invaliding rate with a decreased population. So far as can be ascertained the deathrate among the native community was high Towards the end of the year small-pox broke out in Ashanti, and the epidemic would appear to have been characterised by a high case-mortality. The plague

epidemic which occurred early in the year at Accra, and which spread from there to other towns on or near the coast line, accounted for a mortality of 288 of the total number of cases (336) officially recorded. At Boso in the Volta River district an outbreak of pneumonia in epidemic form occurred and led to many deaths. Such outbreaks have been recorded previously.

Major Bryan, C.M.G., the acting Governor, comments in his report at some length on the epidemic of plague at Accra, which, he observes, is the first recorded instance of plague in a British West African Colony, though an outbreak occurred at Grand Bassam, in the neighbouring French colony of the Ivory Coast, in the year 1899. The origin of the infection remains uncertain. Many theories have been put forward to account for its conveyance to the Gold Coast, but none is supported by trustworthy evidence. The outbreak was not definitely diagnosed as plague until Jan. 10th, but it is practically certain that deaths from plague had occurred before the disease began to develop the character of an epidemic. The fact that the medical authorities did not announce the existence of the diseas an earlier date has been made the subject of local criticism, but the preliminary inquiries and investigations were most thoroughly and conscientiously made by the deputy principal medical officer and his assistants. It is to be borne in mind that these officials had no previous experience of the disease nor were they familiar with the plague bacillus; in such circumstances a degree of reticence was not only reasonable but wise. An authoritative pronouncement that plague has appeared in the midst of a community where hitherto its existence has been neither known nor suspected argues the deputy principal medical officer to possess courage and self-reliance of a high order, and these qualities were no less apparent subsequently in the suppression of the disease. Major Bryan describes in detail the measures immediately taken to deal with the outbreak, and says they were speedily successful. The disease at Accra never assumed the alarming proportions which had been developed in other countries, though the town's sanit ry conditions and certain thickly populated native areas were favourable to the growth of a virulent epidemic. Though the steps taken were sufficient to keep the epidemic in check for the time being, the Secretary of State for the Colonies decided to send out a specialist to advise as to the measures necessary to stamp out contagion, and the colony was fortunate to obtain for this purpose the services of Professor W. J. Simpson. As is usual, the outbreak was associated with an epizootic of plague amongst rodents. A special laboratory for the examination of rats was established at Acera, where Dr. Graham was on various occasions able to acquaint the health committee that areas were infected in which the epi-demic had not yet appeared. The invaluable information thus received enabled the committee to take preventive measures in such localities, with the result that human beings remained free from contagion. One of the most satisfactory features of the preventive measures was the readiness with which the natives voluntarily presented themselves for inoculation by Haffkine's prophylactic, some 35,000 in all submitting themselves to the process. In spite of the measures taken to prevent natives leaving Accra by sea and land, a few fishermen evaded the police by night and left for towns on the coast. In each case the panic-stricken men carried contagion, with the result that outbreaks of plague occurred at Temma to the eastward and at Nianyano, Brewa, and Anamabo to the westward. Prompt steps were taken to deal with these villages, and the progress of the epidemic was checked in each instance, but not before 64 deaths had occurred at Nianyano, 19 at Brewa, and 12 at Anamabo. The Acting-Governor adds: "The courage, determination, and devotion shown by Professor Simpson and the medical staff in preventing the spread of and stamping out the epidemic were worthy of the high traditions of the profession to which they belong, and their efforts were ably and energetically seconded, not only by officers of all departments resident in infected areas, but also by professional men and representatives of the mercantile community who served on the committees of public health.

RADIOGRAPHS OF PULMONARY DISEASE.

To the Editor of THE LANCET.

SIR,—We would ask to be allowed to say that the radiographs referred to in your issue of Nov. 6th, pp. 1397-98, as showing "various stages of pulmonary tuberculosis with striking clearness," were the work of Dr. W. B. Knobel, of Bourne Castle Sanatorium, to whom we were indebted for the loan of them in connexion with the Royal Photograph Society's Exhibition at the New Gallery.—We are, Sir, yours faithfully.

Exhibition at the New Gallery.—We are, Sir, yours faithfully,
Ilford, London, E., Nov. 12th, 1909.

ILFORD, LIMITED.

AN INGENIOUS HATPIN GUARD.

Messrs. F. V. Patterson and Co. of Birmingham have forwarded for our inspection an appliance known as the "Cromwell" Protector for the points of hat and cap pins. It consists of a thin metal hollow sphere, which can be made either of silver-gilt or plated metal, with one of its poles cut off so as to expose the composition with which the ball is filled. This consists largely of uncured rubber, which may be punctured any number of times without losing it grip on the end of the hatpin which it is designed to protect. The patentees point out its suitability for use with nurses' cap-pins, but rightly add that the protectors should not be used in insane wards as they form such attractive-looking bodies to swallow. We have not seen a better pin protector; it is much less trouble to use than those of the older screw pattern.

L.R.C.S. should communicate, in the first place, with Mr. G. Sibley Haycock, director and secretary of the Association for the Oral Instruction of the Deaf and Dumb, 11, Fitzroy-square, London, W., from whom he will probably obtain all the particulars which he We shall be happy to be of any assistance if further information is needed.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Meek.

BOYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

NDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—D. P. Gabell, E. B.

Dowsett, J. Howard Mummery): at 8 P.M.

Dr. J. Eyre and Mr. J. Lewin Payne: Some Observations on the Bacteriology of Pyorrhova Alveolaris, and the Results of Treatment by Bacterial Vaccines.

Casual Communications:

Mr. C. Schelling: (1) A Case of Fracture of the Mandible, set with a Silver Splint made by the Casting Process; (2) Two Cases of Suppuration in the Maxilla, in which the Röntgen Rays materially helped the Diagnosis.

Mr. Stanley Boyd: A Case of Unilateral Overgrowth of the Lower Jaw. (The patient will be present at 7.30 p.M.)

MEDICAL SECTION (Hon. Secretaries—A. M. Gossage, A. F. Voelcker): at 5.30 p.m.

Paper:
Dr. F. Craven Moore and Mr. R. L. Ferguson: The Rôle of Fats in the Treatment of Functional Disorders of the Stomach.

THURSDAY.

NEUROLOGICAL SECTION (Hon. Secretaries—E. Farquhar Buzzard Wilfred Harris): at 8.30 p.m.

Hughlings Jackson Lecture :

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed esclusively "TO THE EDITOR," and not in any case to any entleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FIGATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

Until the end of the present year copies sent by post will be charged at the rate of $7 \pm d$. inland and 8d. abroad.

Commencing with the issue of Jan. 1st, 1910, the rates of subscriptions, post free from THE LANCET Offices, will be :-

FOR THE UNITED KINGDOM.
One Year 21 1 0
Six Months 0 12 6
Three Months 0 6 6

Three Months 0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA-Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

The FitzPatrick Lectures

GREEK MEDICINE IN ROME.

Delivered at the Royal College of Physicians of London BY SIR T. CLIFFORD ALLBUTT, K.C.B., M.D. CANTAB., F.R.S.,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

LECTURE I.

PRESIDENT AND FELLOWS, -In calling me to deliver the FitzPatrick lectures you have done me much honour, and it would be an ill-timed, however genuine, a diffidence which might seem to disparage your election; I may, notwithstanding, hesitate for a moment, as I regard the dignity of this place and as I admire the services of my predecessors. In them we have had examples of wide and sound learning, of biographical skill, and of anecdotal charm which are above my hope, and I trust outside your comparisons. For such lists I am unarmed. To original research I have no pretensions; I am a child in scholarship. Yet in some converse with letters my tastes, if not my talents, have attracted me to the development and propagation of ideas, and it will be my endeavour to present to you some broad sketch, thin and partial as it may be, of this evolution as illustrated in the history of medicine.

On the dark and stupendous background of Rome, from the foundation of the City to this day, has been displayed, as on no other canvas, the procession of those forms and those forces, innate or acquired, of science, art, politics, and religion, by the conflict and interpenetration of which the nations of modern Europe were made, governed, and

inspired.

We have our moods in which we ask ourselves if history is a fruitful study-nay, indeed, if it be not a sign of an uncreative or even of a decadent society. If our hearts are opening more and more towards the promises of the future, why should we be hankering after pictures of the past? Did the Greeks of the Parthenon regard the earlier temples whose fragments they built into their battlements, or did the Greeks of Sancta Sophia painfully restore the ruins of the Temple of Constantine? Did not the builders of St. Mark's or of St. Paul's without the Walls for their own creation even demolish the monuments of the past, as the painters of the generation of Massacio obliterated the frescoes of their fathers, and as the scribe of the cloister buried the silver uncials of some rare Pagan manuscript under his ruder record of the Gospels? Was it not, then, the wistfulness and pathos of a nation passing its prime which first tuned the notes of Virgil to a historical theme? Was not his patriotism the passionate clinging to a form which was passing away? And when our own poets take up the chant of Où sont les neiges d'antan, is the voice one of joy or of foreboding? In our saner judgment we shall answer with some boldness that the study of history need be no wistful turning back from the plough to yearn after golden ages which never were; that history is much more than the raw material for pious platitudes, and regrets, and picturesque instances. The study of history must become the orderly reflexion and method of a society, past its golden childhood indeed, yet parting with this blessed blindness, to enter upon a nobler life, in the maturity of reason and responsibility. To sap our ideals, as Roman history and all history show, does mean decadence; and it is for history to reveal the unity, the spirit, and the growth of all human ideals; and to maintain our standards. Nay, may it not, as at the Renaissance which drank deep of the past, by a kind of psychical

had grown up on tradition, on its instincts as the ants and the rooks, must, if it is to interpret its own nature and to shape its future, now take to learn at first hand the origins, the course, and the principles of its growth, wealth, and activities, and moreover to apprehend the vast scale upon which not only material but spiritual forces operate. For time present can scarcely be said to exist: Dum loquimur fugerit invida actas. From history, "a longitudinal section of human life," as Ilberg calls it, we shall apprehend how hideous is the waste in the phases of unreflective social development; and how progress may be made, not by scrapping one human society or devouring another, but on lines of continuity in free spaces of expansion, and by disengaging and delineating the methods by which a rational creates an economical evolution.

Thus truly it is that we are assured by our professorial colleagues that history is a science, a truth of which we are made painfully aware when nowadays from the Capitoline Hill we look down upon the stonemason's yard still bearing the name of the Roman Forum. Science looks to the future it is true, but to the more material future. It has little or no concern with values, but with means rather. Science seeks not exemplary instances; for science no fact is despicable because it is little; true and false opinions are alike significant of the mind of the past. History is a science when by its methods we analyse our past; it becomes an art when for our inspiration we recreate the ideals which time had devoured, and when as politicians we apply them to life. With the disengagement of reason there is no doubt in society, as in the individual, some loss of spontaneity; moreover, the creative and the deliberative impulses instead of uniting in fertile marriage are but too apt at first to get in each other's way, to act at cross and even contrary purposes, and to mistrust each other, so that each faculty drags its images and counterfeits from the past to impose them upon its own times. Thus we are provided with static monuments of the past for admiration and example, rather than with the breath of its dynamics for our life, strength, and beauty. But the historical philosophy of an age gone by did not consist in its fashions nor even in its ostensible systems of logic. Of course, no category which becomes an instrument of thinking can ever become obsolete, but to imitate the past, as our modern mediævalists would do, is but a masque; as to form and custom history never repeats itself; it is in a restoration of the motive and the spirit of the past that we must cherish the perpetual fire to animate and renew the ever-changing forms which are never repeated. Man should ever be more and mightier than his past. It is, then, the mediatory office of such lectures as these to interpret the past sub specie historiae; to construct a historical or comparative criticism of life; to bring life and flexibility into law and logic, to warn us against the clumsiness of interpreting the ancients by translating our ideas and ways into theirs, as men have imputed Christianity to Virgil and Bacon to Shakespeare, and as the earlier critics of the Bible, in the immaturity of the historical sense, occupied them-selves with judicial criticisms of its contents: or conversely to warn us against the illusion of tricking out modern ideals in ancient trappings. From history we have to learn not only what our ancestors conceived and made, but also why they thought and acted so.

Once more, both as science and art, both in reflective and developmental criticism and in regenerative idea, does not history make yet another kind of appeal to us? mountaineer, familiar with a group of peaks as they had long appeared to him in his accustomed haunts, where again and again he had climbed their summits and explored their recesses, takes a new journey; he traverses a great valley, outflanks the hills, and suddenly from a strange vantage the once familiar peaks burst again into view, but with fresh features and in new relations. He gazes wondering at the transformation as it were of some wary herd which, while he was making his circuit, had silently faced round to watch him, but yet were not the same. In some solemn maze they have wheeled about each other, and have turned other faces to the wanderer. Thus, in no extravagant figure, I hope, I have sought to convey to you the new, the strangely new, regard of the constructions of man when, by our adventures in history, we come round to see them from other quarters and other prospects. We knew our own group of ideas; we had, if you please, scaled its summits and explored its recesses; but these ideas

cross fertilisation, infuse in us the rudiments of a new epoch? It has been said that as an emotional and instinctive being man is dateless, but as a reasonable being that he is of yesterday. In its youth society is sustained by authority—by authority of king, priest, or philosopher; myth is then its history; but when authority ceases and self-consciousness awakes historical reflection must begin. The society which ¹ On the occasions of these lectures portions only of a larger manuscript were read. For some consequent incoherences the author hopes to be parloned. No. 4500.

now reveal themselves with fresh features and in new relations. And thus the real forms and organic plan of our own age are manifested to us as never they were before: and, whether as artists or geographers, we discover how partial was that knowledge, even of our own life, which before we had believed to be intimate and comprehensive. We do not know the full truth of our own folk, our own walks, and our own phases of life until by travel of time and space we have outflanked them, and discovered their form and growth by other avenues and in other illuminations.

Now of medicine the history is, or until our own day has been, part of the history of natural science; and, indeed, the source of that philosophy of history which regards human societies as conditioned by circumstances; a conception in which Hippocrates preceded Comte, Buckle, and Taine. He, therefore, who would interpret the documents and the history of medicine must be at least initiated into all history. Physicians of the past, as of the present, were made of common humanity, and their life in medicine was not alien from their life, and the common life of their age, in love, work, and war. In the medical historian, therefore, the sympathy of humanity must be added to the accuracy of the scholar, and these to a technical equipment in our art. And in the age of Leonicenus, of Linacre, of Caius, of Fuchs, of Foesius, of Mercurialis, we made at the Renaissance a famous beginning. But the humanists, never really friendly to science, soon began to play us false. Disliking the raw anatomy of knowledge, with what they called "The Classics" they built a walled pleasaunce for themselves and dwelt therein, raising florists' blooms and out flowers, till Wolfe and Schliemann began to throw stones over the fence. They were of the kind of the old grammarian who said there could be no interest in a period when dπò governed the accusative.2 In classical periods we realise our traditional ideals, but if they claim by their stationary contemplation to govern development they stifle the spirit of history, not only in forms of words and artificial categories, but also by an assumption of "common sense." Now "common sense" never verified premisses, discovered origins, or interpreted natural means, orders, or ends. curious instance of this claim of common sense peeped out in a recent Times review of Mr. Jones's "Malaria and Greek History"; by this faculty the literary man supposed he could settle Mr. Jones's problem without even the pretence of repeating and verifying his researches. The study of language deals only with past experience; the past of the whole of mankind and of its chief persons, yet still of the past. New and enlarging experience is to be had not by common sense, but by new uses of the senses; and for the record of these fresh receptions new words, new phrases, new combinations of old words will be required. Thus a nation, or an individual, which is not continually returning to the direct uses of its five senses on advancing problems may collect experiences, but makes none. No small part of the labours recorded in our classical journals may have its narrow utility, but, intellectually and ideally regarded, seems to me to rank with chess problems. As studied statically, literature is deprived of the keys of growth, and of those tests of affinity whereby we learn to discriminate the formal and incidental from the essential and spiritual.

Although, then, in the first ardour of the Renaissance medical texts sprang into discovery, some were printed, and Medicine received its place in the universities as a liberal study, yet humanist fastidiousness so prevailed that no original medical texts followed those of the sixteenth century; nor did eminent scholars and commentators labour much even upon these. Naturally, therefore, among the incunabula medical history settled on its lees; the baser utilities prevailed, and, in the eclipse of Greek, Latin texts were more in demand. Hence, beside the invaluable recovery of Celsus, sprang up a thick crop of Isagoges, Articellas, and crude Latin renderings of portions of Hippocrates, Galen, Soranus, Rufus, and Oribasius, often derived through the anything but achromatic medium of Syriac, Arabian, or Hebrew. Thus, as I have foreshadowed, forms were copied; but the spirit—the return to nature—was

not imparted. The cruder stuff came over, the finer evaporated.

How hardly the sacerdotal crust of the false Aristotle and Galen was cracked and split up I endeavoured in my Harveian Oration to illustrate. And even when by the sledge-hammers of Vesalius and Harvey this crust was cracked the awakening was slumberous. In my own reading for these lectures I have been surprised to discover the faults of the texts, the poverty of criticism, and the sequacious dependency of medical historians one upon another, even to verbal repetition. For the edition and interpretations of our documents, as I have hinted, and as liberg and Wellmann have declared, the too rare combination of physician and scholar—as in our own Adams and Greenhill—is required. So it has been left to our own time-I had almost said to our generation-to see the first great edition of a medical classic; I scarcely need say that I refer to the Hippocrates of Littré. But since then our progress has become more lively. In Greek we have had the Oribasius of Daremberg, Ideler's * Physici et Medici Gracci Minores, Wellmann's Dioscorides, Puschmann's Alexander; in Latin three or four critical editions or commentaries of Celsus, and so forth.⁵ To Littre and Daremberg in France, and in Germany to Diels, Ilberg, and Wellmann we are largely indebted for the impulse they have given to the re-editing of medical texts, and for the fertileculture, both linguistic and scientific, which they have brought to the task. I wish we could show in this country a like accomplishment. It is mainly, I believe, to Professor Diels, upon whom the other day in Cambridge by bestowing an honorary degree we honoured ourselves, that we owe the great project of a Corpus Medicorum Graecorum from Hippo crates to Paul, now undertaken by the Berlin University under the auspices of the Associated Academies, and initiated by the Excerpta Vaticana of Philumenos, edited by that distinguished scholar, Max Wellmann. But after all our collections, probably after all we can hope to collect hereafter, the history of medicine will resemble the geological record in its breaches, in its fractions, in its faults, and in its embeddings of ancient and precious débris in later conglomerates. Cicero's conditions "excipiente memoria, prodendisque monumentis" are in our history too often wanting (De Div., I., 6).

I have regarded Rome as a vast dark background against which were projected the processions and conflicts of human ideas, as they gathered from east to west to pass before her, or through her, or to be taken into herself. It is necessary to my purpose then to see how this background was laid in; though in this place a survey of Roman origins must be so curt as bluntly to state for truths a set of opinions which, however probable, have as yet scarcely more than a provisional acceptance. The original, the lowest, and still perhaps the thickest stratum of the peoples of the region I may briefly indicate as Mediterranean, was and is a small slender dark race, long skulled, delicate in limb and feature, probably of neolithic descent, who buried their dead. This race was vivacious but not robust in body; not of large political capacity, being more factious than warlike, more clannish than national; vain and fickle but attractive, sociable, affectionate, even tender, yet wily, and with strange red veins of cruelty; but above all endowed with imaginative or at any rate with artistic gifts beyond the rest of the children of men. In the great peninsulas and myriad islands of the inland sea, and no doubt over a larger area, this race established civilisations of high culture, especially of artistic culture, which in its various modes and places is now known to us under such names as Pelasgian, Minoan, Aegean, Attic, Ionian, and so forth.

Now we are to suppose that northwards of this Mediterranean world there was an area of high pressure occupied by prolific races of alien stock, of greater physical strength and hardihood, of larger political aptitude, and perhaps possessed of weapons of iron. These various kinds of northmen were fair of complexion, and on the whole bigger of body; in temper warlike, dominant, stubborn, and ruthless.

² I find this construction was not a mere pedantic pleasantry. Liddell and Scott do indeed ignore it with severity; but in Sophocles the lexicographer I find many examples from Alexandrian and Byzantine Greek—for example, Porphyry, Hermas, Leo Grammaticus, &c.

² Science and Medieval Thought. By T. C. Allbutt, Harveian Oration, 1901. Cambridge: University Press. ⁴ Ideler published this work in the last year of his life (1841-2) at the age of 33. In him we had to lament a death even more premature than

age of 33. In him we had to lament a death even more premature than of Daremberg.

5 Another edition of Celaus is announced by the Saxon Society of Sciences under the care of F. Marx. There are rumours of the discovery of another and much earlier MS.

In contrast to the earlier race they burned their dead, and thus in later days the two customs continued side by side. We must presume that some period of time, probably a very long period, elapsed before, by their own increase or by the pressure of other races upon them, these fiercer northmen or mountaineers, as in the cases of Elam and of Assyria, became restless; pressure rose higher and higher, and the thrust southwards irresistible. Especially, as it concerns us at present, their periodical irruptions began and increased by way of the Balkans. Under the various names of Achaians, Thessalians, Dorians, Siculi, Umbrians, Sabines (probably akin to Umbrians), Oscans, and so forth, kindred tribes of warriors swept downwards on the peninsulas of Greece, Italy, and Spain, slaughtering more or less, but for the most part subduing and enslaving the more slenderly built dark people probably already enervated by peace and indolence. The later descent on Rome of a coalition of "Keltic" and other tribes under Brennus is more within common memory. "Gauls" and "Kelts," in one shape or another, were probably continual immigrants.

It is important to remember that, although in the Greek peninsula the Dorians swept downwards to Sparta and the South, into the southern half of the Italian peninsula the northern tribes scarcely penetrated. From geographical causes this area was more open to occupation by way of the sea, and was thus invaded from Greece; and the history of the flourishing harbours and cities of Southern Italy indicates that it was not malaria which at that time arrested or checked the immigration from the north, but the natural features of the land and coast. Southern Italy, in the times of which we are speaking—say from c. 570-280 B.C., when these cities submitted to Rome -was not Italian even in name, but in name was Magna Graecia and in character was Greek; and this character, until blighted by malaria, is maintained. The Italiote Greeks held their general assembly at Heraclea; the later Thurium was an outpost of Athenian The people of this region were greatly reinforced, moreover, by the flight of kindred folk chased from Greece to "Saturnia" by the Dorians and their kind. In the time of Augustus Dr. Verrall speaks still of the Hellenic city of Naples, Hellenic in its society, culture, and festivals; it became filiated to Rome late and reluctantly. I have long held the belief that rivulets of this Greek blood and culture. choked indeed by oppression, disaster, and pestilence, were yet one source of those springs of new culture which broke forth in this region in mediæval times—of the inspiration, so various in its manifestations, of Paulinus, of Telesius, of the physicians of Salerno, of the savants of Naples, and possibly of the Pisani. Frederick the Second, by the library he collected, fed these springs, but he did not make them. Dr. James tells me he thinks that before that collection there were not a few Greek MSS. in Calabria. The natives of Calabria of 1155 A.D., says Gibbon, were still attached to the Greek language and worship, and in mediæval times passed themselves off as Greek. I may note that the first professor of Greek in a Western university was a Calabrian. Legrizio Pilato, at Florence, who pretended to be a Greek of Thessalonica. He is said to have translated Homer into Latin for Petrarch. If I remember right he was forcibly described by Boccaccio as a dirty, grumbling little beast. He had the honour, however, of being killed by lightning on board a ship in the Adriatic. The archaeological spade work so much needed in Calabria will doubtless reveal hereafter in richer measure the distinctively Greek works and qualities of this region; and it will do more. Even to-day the Greek walls and tombs of the fourth century B.C. laid bare on the desolate waste of Metaponto read us not only the old homily of the mutability of human things, but the new and unlearned lesson that without Medicine there can be no abiding city.

About the time of the foundation of Rome then a large under population of the slight dark people was submitted to the ascendancy of more vigorous northern tribes, of whom Umbrians and Sabines may be taken as types. But this was not all. By way probably of the Po, but thence extending

over the Apennines, a strong, a strange, and a gifted people, from whom the region of Etruria derived its name (Rasena in their own tongue), had in some foretime of history, perhaps about 1200 B.C., established themselves by fortified cities in northern and central Italy. As from this race Rome took much of its nature and customs, we must digress for a moment to learn what we can of the obscure story of its origin and affinities. We shall consider hereafter the close connexion of Latin Medicine in its later history with Asia Minor, a side of the story which the recent essay of Mr. Hogarth on Ionia has set very ably before us. To proceed after my summary fashion, we will regard Asia Minor as controlled by a great power whose history lies in the mists of the past, every key to whose language is lost, and, indeed, had disappeared in Strabo's time. This power for we can scarcely indicate it less vaguely—was in its might continental rather than of the seaboard, and the seat of its power in inland cities. It seems to have consisted in a lordship of Aryan invaders from the North, by way of the Black Sea, over native races which in ancient times, under the names of Carians, Lydians, and the like, occupied also the Levantine seaboard; and ancient records and modern researches indicate that what must have been a vast host of these people, Carians or Lydians, thrust out, perhaps, by the North Cappadocian overlords, whether by sea, as may be supposed from their place of origin, the tradition of their advance from south to north, and their Italian history as sealords, "pirates," and great traders, or, as Mommsen supposes-less probably salra tamen ejus laude, by the Balkans and Aquileja, established themselves in Italy as Etruscans and brought with them not only some literature, some astronomical science, and a rich art, but also customs and ceremonies of such potency and tenacity as to have entered into the construction of ancient Roman society, so deeply as in no small part to have survived in the Roman hierarchy from then till now; for the Roman Ceremonial, aswe see it, is not wholly, perhaps not chiefly, "Aryan." on the physical side, in their fleshy bodies ("Tuscus obesus"), almond eyes, big noses, and gorgeous tastes, so in their caste and stationary policy, customs, divinations," magical and sepulchral ceremonics, dances, and festivals, this people was in character strongly oriental; and their divinations may have been witnessed by Abraham himself on his entry into Hebron. Their trumpets are said to have been Lydian, their pipes Phrygian. "Tuscos Asia sibi vindicat" was the record of Seneca. Profoundly as the Etruscans differed from the Umbrian or Sabine Roman, especially in respect of artistic faculty, yet in warlike energy, military caste, doggedness, hard and exclusive temper, aristocratic supremacy, and curiously enough in the status of their women, the two masterful races had so much in common that by their fusion Rome was created, and a permanent ascendancy established over the weaker but still multitudinous and, no doubt, somewhat mongrel people, or plebs, which we have regarded on the whole as aboriginal. We read of the "parcus Umber"—the closefisted Umbrian; of the "tetrica et tristis Sabinorum disciplina "—the sombre and puritanical discipline of the Sabines, who were the backbone of old Rome." The patricians and their flamens seem to have worshipped Sabine deities. In broad outline, then, the background of Rome, for us the soil on which Roman medicine was to be cultivated, consisted of the original small, dark race,

* Divinations by entrails, flight of birds, &c., rather than by the astrology of the Chaldeans. Certain of the gods of ancient Rome were

O'Vide paper by Mr. Stuart Glennie (meeting of American School in Rome, December, 1908), on a tomb of Pelasgic origin at Quinto Fiorentino (near Florence) which gives further evidence of a Pelasgic period between (as the author puts it) "the Ligurian and Etruscan epochs of Roman (Italian?) history." If I do not enter into such vexed questions as of the round and long-headed dark people of mid-Europe, and of Gael and Goidel, it will be readily forgiven me.

That ornaments and utensils like those of Etruscan provenance have been found in Rhaetia is true, as I myself observed under Professor Pigorini's kind instruction many years ago, at Matrai, Trent, and elsewhere. But all bronze civilisation was not Etruscan. Moreover, the Etruscans burled their dead; the Rhaetians, like all the Hallstadt and Villanova folk (Umbrian') cremated. The Sabine families in Rome cremated. At Matrai bronze fibular, coral and amber have been found together. Etruscan sway probably extended far beyond its realms, as, for instance, to the L. Benacus, the "Lydian Lake" of Catullus. The wonderful beauty and genius of their crafts are preserved for our admiration in all great museums, especially in the Vatican, in the Castellani and in Florence, and their work is described in Dennis's "Etrufia" and later books.

8 Divinations by entrails, flight of birds. &c., rather than by the ⁷ That ornaments and utensils like those of Etruscan provenance have

astrology of the Chaldeans. Certain of the gods of ancient Rome were of Etruscan importation.

9 The "Lanuvinus ater atque dentatus" ("with fine teeth," as we gather from the context) was probably "Iberian." This passage, to which I have lost the reference, alludes to the practice of rinsing the teeth with urine; the whiter the teeth and the redder the gums the more of this disgusting lotion must have been used! Urine has not even yet wholly disappeared from the nursery pharmacoporia; there are still crones among us who would use it, like "fasting spittle," for children's sores, and especially for childlains.

reduced to formal or virtual servitude, degraded but still vivacious and factious, and of an ascendant and irresistible aristocracy, mainly of northern invaders, but interpenetrated by another ruling race of oriental habits. It is remarkable, and belongs perhaps to the military avocation of Rome, that while in religion the omens and auguries of the Etruscans persisted and even prevailed, their notable artistic qualities, unless in the mighty architecture 10 and cloacae, seemed under military rigour to have been blighted, or in later times to have been stifled in luxury until the Renaissance, when in Tuscany especially it reappeared. In early times they were warriors, hunters, pirates, and athletes; we all remember the later description of them : -

> "Semper inertes Tyrrheni; At non in Venerem segnes nocturnaque bella,
> Aut ubi curva choros indixit tibia Bacchi;
> Expectare dapes et plena pocula mensae
> Hic amor, hoe studium."
>
> Acn., xi., 732 (vid. et Catullus, xxxix., 11),

Whether in war, in religion, in literature, or in any high purpose of man, when forms are not kept fluid by an ardent and expanding spirit, induration and corruption set in. We have spoken of one of the lessons of history—that so long as we keep mind and passion free forms will take care of themselves and be transformed in ever new revelations of beauty and strength. Thus of the so-called Iberian or Pelasgian people, the artistic and imaginative qualities, which in all the Ægean cities were notable and in Greece attained to incomparable achievement, in Rome seem to have been crushed under the weight of the State; even the melancholy harp of the oppressed seems to have been muffled or silenced. Yet, such were the undying gifts of this brilliant race to an ungrateful world, that wherever they broke forth again into some freedom, in realms—as in Gaul and in Spain where the fury of the northern invaders was appeased; or in remoter fastnesses such as Brittany, Wales, and Ireland, where they were, so to speak, squeezed out at the edges of the conquering principalities, their song was heard again; no longer, indeed, joyous, dominant, supreme, but wistful and symbolic, dreamy and unsubstantial in the sense of uncon-densed mystery rather than of chaos; yet, as in the Ireland of the eleventh century, soaring again; in Alfred and Charlemagne educating not kings only but dynasties, and in France, in Belgium, in Franconia, in Switzerland, in North Italy (Bobbio) teaching and illuminating the new Europe; so that to this remnant in the far west, as to Greece, the old phrase may be adapted 11—Hibernia capta ferum victorem cepit, et artes Intulit agresti. Their creative work, like that of the Jews, if it has not gone to the making of nations, has built up the spiritual kingdoms of mankind.

And of this race, not as the artificially degraded plebs of Rome but as the spiritually free, if politically sub-ordinate, Pelasgic Ionians of Greece and Asia Minor, we have to speak as protagonists of Medicine in the arena of Rome; Rome as we have seen her grow up-austere, masterful not in ideas but in material predominance; yet, being ignorant and infused with Oriental affinities, superstitious, and in religion ritualistic and pharisaic; a people entrenched also in a folklore and a folk medicine of their own, and worshipping a mob of pallid deities each, as elsewhere so in Medicine, personating rather than creating not only every chief system and function of the body but every stage of each. For each stage of labour there was its peculiar deity; and of limbs even the harmless, unnecessary navel had its divine warden. Thus, as Bloch says in Pagel's "Handbook," "the religious cult of Rome contained an entire pathological system"—and consecrated it. Mommsen had said also that this religion contained every function of life. Even the itch was not without its goddess. Thus for the early and religious Roman a scientific medicine was impossible. How in the decay of faith and by the immigration of the busy, curious Greek, this "cake of custom" broken up we shall consider hereafter. Soranus bluntly declared that the obstetrician should be "άδεισιδαίμων." It

were scarcely worth while for the purpose of these lectures, even if I had the mythological knowledge, to distinguish in the chthonian and olympian hierarchies between the gods of the Etruscans and those, on the one hand, of the aborigines, and, on the other, of the northern invaders. Into the populous circles of Greeco-Roman divinity almost any new god was welcome who would play in the old game. The Etruscan worship was, however, in the main nature worship, and its deities chiefly chthonian. And among all the aboriginal Mediterranean races the chief deity was, and still is, the great and fertile Earth Goddess-Dea dia, under various names-Cybele, Rhea, Ashtoreth, Diana, Orthia of the Spartans, Artemis of the Ephesians, and so on. In his rare hymn to Diana Catullus, after saluting her as the mistress of woods and fountains, as Luna, as Trivia, as the patroness of corn and fruits, and as Tu Lucina dolentibus Juno dicta puerperis, exclaims:

> " Sis quocumque tibi placet, Sancta, nomine : Romulique Antiquam, ut solita es, bona Sospites ope gentium." Catull., Carmen. Sec ad Manam.

And, as Mr. Hogarth points out, in the General Council of A.D. 431, when the Nestorians were condemned, the Madonna had taken this place in the hearts of the people, and has held it ever since, both in the Roman and the hastern Church. And I may remind you of a passage in the first volume of the "Stones of Venice": "The Madonna is in great glory, enthroned above ten or dozen large red casks of three-year-old vintage, and flanked by goodly ranks of bottles of Maraschino and two crimson lamps in the evening, when the gondoliers come to drink under her auspices, she will have a whole chandelier."

We cannot wonder that the Solemn City, the seat of so grave and haughty a race, mistrusted and repulsed the plausible and versatile but yet alert and intellectual Greek. When Greece was at its height Rome was the land of the soldier, the peasant, and the small trader; a people without art, literature, or philosophy. It has been aptly said that the relative geographies of the two peninsulas, Greece and Italy (for the elder Greeks the land of Hesperia), especially in respect of harbours and seafaring, were such that they turned their backs upon each other; and the mission of Rome was westward. Until the third century, except at Cumse and a little later at the remoter Ancona, the only fair harbour on the Adriatic aspect, the contact of Greeks with Rome, if any, was only by way of the southern provinces. It was not until four centuries after the time when Rome was little more than a dyke and a palisade commanding an agricultural domain that she established diplomatic intercourse with Greece, 12 and that a Greek freedman of Tarentum became the earliest of Latin poets. After Metapontum, Tarentum, a great city upon a rock, founded by Dorians of Lacedæmon in 708 B.C., produced between 400-330 B.C., its finest coins, and led the southern confederacy until its reduction by Rome in 272 B.C.

So far, then, as we have analysed the sources of Roman medicine we discover a broad and deep but far from pellucid stream issuing from and compounded of the folklore of the small dark people we have taken as aboriginal, of the Etruscans, and of the invading northern tribes whom we may indicate roughly as Thessalian. It is obviously impossible, were it worth while, to trace Roman folklore farther and severally upward to these three constituent founts; we must content ourselves with some note of its characters as we find them in respect of medicine when Greek physicians first appeared in Rome. Into that main stream were now poured three fresh tributaries. Two of these tributaries were medicine of the Greek clinical or Hippocratean school, which again was twofold: The earlier current of Italo-Greek origin, dating from the sixth century, deriving from the following of Pythagoras, Empedocles, Philolaus, Alcmaeon, at Achaian Croton, a school second only to Cos, from Metapontum, also from the school of that great physician, Diocles of Carystus, probably at Athens; and the later but more direct current, reinforced by the Alexandrians, of which Celsus is our exponent and eminent example. The third tributary was

¹⁰ It is said that the great temple of Jupiter on the Capitol was of Etruscan architecture: but great examples of it in enormous city walls, uncomented but everlasting, in the arch with uncomented keystone, and in exquisite specimens of jewellers work are well known to all travellers interested in ancient history. The Roman house is supposed

to be on Etruscan plan.

11 To speak of "wedding the Celtic vivacity to Greek technique,"
unless in certain late and special instances when Greek had shrunk
into a "technique," seems to me, ethnologically speaking, misapprehension.

¹² The well-remembered embassy of Diogenes, Critolaos, and Carneades to the Roman Senate praying for the reduction of an indemnity. The decree of expulsion of the "philosophers," a few years previously, must be taken as a sign that Greek ideas were then spreading in Rome

the Hellenistic medicine of which Asclepiades was in Rome virtually the first, as Galen was the chief example. In an inchoate society, founded as was Rome, in the year 759 B.C. on some federative basis, the faculties of religion, law, custom, medicine, agriculture, could not be fully differentiated; and we shall see how long a time it took to release medicine from other functions, and especially from religion and custom; and even then how vehement were the later conflicts and reactions between clinical and scientific medicine, priestcraft, and folklore.

Folk medicine, whether independent or still engaged with religion and custom,13 belongs to all peoples and to all times, including our own. It is not the appanage of a nation, it is rooted in man; in his needs and in his primeval observation, instinct, reason, and temperament. Still it is largely modified by the kind of man; for instance, in the Greek folk medicine was soon separated from theurgic medicine, and even from mysticism; so that a professional medicine was more quickly conceived and built up. The necessarily sceptical attitude of professional medicine whereby the infinite complexity of function and the baffling conditions of observation are understood, an attitude which even commended it to the subtle, inquisitive, and irresponsible apprehension of the Greek, was for the ceremonial and slow-witted Roman even more intolerable than it To folk is for our own fellow-countrymen to-day. medicine doubt is unknown; it brings the peace of security. If infallibility failed! why, the game was not played properly. From Cicero we learn, as we learn in modern Rome, the potencies of an inflexible ritual exactness. First of all, the right deity for the job had to be discovered; let us say, for fortune Mercury, Neptune for a voyage, Robigus against the mildew, and so on. Then he tells us how there was one priest for ceremony, another for formula. If a word was altered, if a flute-player rested, or if an actor stopped short, the rite was broken; all must be recommenced. Prayer and personal observance had to be no less pharisaic.14 So in medicine; the proper god or godling had to be ascertained; then the proper formula of magic utterance to accompany the drug or operation, which, as we read in Cato and elsewhere, was to be recited with rigid precision.

Of supernatural or magical observances the more specific were "binding and loosing," the virtue of laying-on of hands, the discovery of names, lustrations, holy wells, dreams and their interpretation, temple incubation with its corresponding donaria, and the fantastic notions of signatures and symbolisms, of sympathy and analogy, of talismans; all of which observances entered deeply into early Roman as into other folk medicine of those and of later times.

These several veins of folk medicine, worked out at some length, were necessarily omitted from the lecture.]

Having now indicated rather than described the theurgic and magical elements in Roman medicine, I will with your permission step back to take up my story again with the household and folk medicine, and particularly with the practice of Cato the Elder. The more remote and secluded the society the more freely domestic medicine flourishes, as common experience tells us. In the agricultural and pastoral provinces of Scotland, where journeys were long and toilsome, the housewife's medicine closet was the busier. The lairds and their wives "doctored and drenched themselves and their dependants with all sorts of weird and wonderful decoctions," mixed according to manuscript collections of recipes handed down from generations beyond memory. And in the English counties this selfreliance was not much less, especially among those of the gentry who rarely travelled far from home. I remember hearing that the great sportsman, Mr. Meynell, to get rid of the gout for a hunting day, would take on his own counsel two strong calomel pills and a teaspoonful of colchicum wine in a glass of hot gin and water; while the only stimulant he took with him in his flask was tincture of rhubarb.

is in some such light as this that we must regard the medicine of Cato-as one of the many arts and home industries which in early societies are not yet differentiated. Though not noble yet probably of old Sabine stock, Cato, by his rude honesty, energy, strength, and austere ascendency -ferrer prope corporis et animi, as Cicero says in the De Senectute-rose from quaestor to be aedile, praetor, consul, and censor. Like nearly all the old Romans, and like many Swiss landholders down to our own day, before the importation of Sicilian and foreign grain, and presumably before the introduction of malaria, he "tilled his own lands with his own hands." Now we learn from Pliny that Cato practised medicine by the guidance of a certain Commentarium, or traditional recipe book in many chapters, extant in Pliny's time (Hist. Nat., xxix., 8), the contents of which, so far as conveyed in the Historia Naturalis, are partially known to us. Many of the prescriptions were futile, many were filthy, though in later generations they became filthier and filthier; some, however, were efficacious enough. Local and general narcosis were practised after a fashion. find the same or similar recipes in Dioscorides, Scribonius, and other such collections, we linfer that Greek and Roman drew from the common sources of an ancient medical lore.

The best known of Cato's medical means are the homely prescriptions of cabbage and wine in various forms for almost all internal complaints, and his magic sentences, gibberish 15 which was uttered over both surgical and medical cases to expedite the cure. Now, although I have not met with the suggestion, it must have occurred to many medical readers that Cato's cabbage, in days when fresh meat was not to be had in winter, or certainly not by the lower orders and the slaves, probably acted very effectively as an antiscorbutic, and that by this virtue its repute as a medicine was made and sustained. The cabbage - Olus under its more general name, more specifically Brassica—was regarded seriously as a remedy long before Cato's time; by the Etruscans, for instance, and by the Greeks—at any rate, by the Sicilian Greeks of the tradition of Pythagoras, as by Epicharmus, a pupil of Empedocles, who wrote a treatise in the Doric dialect in which cabbage was thus recommended 16; and, indeed, by physicians of no less distinction than Diocles, and Chrysippus the master of Erasistratus. If, then, Cato erred, it was in good company. The variety in use as a medicine in early times was probably the colewort, or sea cabbage, which has a slenderer leaf and a more bitter taste.

It may be asked why we should occupy ourselves with Cato, who, whatever his merits as a patriot, was, from the point of view of scientific or artistic culture, a gruff, obstinate, narrow-minded rustic, whose violent denunciations of Greek physic were but illiterate prejudice. I think in this respect historians have done Cato some injustice. In no small part we, as physicians, have derived our impressions of Cato from the babbling of Pliny, who had the vanity and garrulity of Boswell without his reverential sincerity. But in Plutarch we have a truer appreciation of Cato. It was said that he took to learning Greek "in his old age"; "belike fearing," as Sir Philip Sidney puts it, "that Pluto understood not Latin"; or, as Professor Mackail suggests, because of his admiration for the younger Scipio. But Cato was no such ignoramus; on the contrary, for his time he was a learned man. stoicism, stern and inhuman as it was no doubt when compared with the milder interpretations of Panaetius, he owed nevertheless to Greece. And, before Celsus and Varro, he was an encyclopedist—a "summist," whose chapters, not only on military matters and agriculture but also on law and history, were extant and respected in Cicero's generation. After his African campaign, and some nine years before his consulship, he discovered Ennius in Sardinia, brought him to Rome, and learned Greek of him at an age nearer 30 than 80 years. So that his Greek studies, were they more or less, extended over some half-century of his life. So far, then, from regarding Cato as a narrow and arrogant boor, may we

¹¹ Mr. Warde Fowler points out that the rites of Rome, whether Btruscan or Old Italian, are to be regarded separately from the religion, much of which came from other sources.

14 I read this year in a certain church, and over the signature of an eminent archbishop, that 40 days of Indulgence would be obtained by saluting a particular crucifix, and reciting one pater and one ave. But for one unable to go to this image 20 paters and aves would be required: one for each of the 14 stations of the Cross, five for the five wounds, and one "à l'intention du saint Père." Thus tenacious is ritual tradition. In the recent controversies around the death-bed and burial of the late Mr. Tyrrell much curious matter of this kind was notable.

¹⁵ From our point of view, gibberish; yet even gibberish may have its specific interest. It is probable that not Cato's incantations only, but those also of other times and peoples, are the degraded remains of some ancient tongue. Cato's "Daries, dardaries, &c." may be remnants

¹⁶ Vide Schneider, Script. rel. med. Brassica = $\kappa\rho\delta\mu\beta\eta$, "crambe repetita"; in the late Greek lexicon of Sophocles, $\kappa\rho\delta\mu\beta\iota\nu=\kappa\rho\delta\mu\beta\iota\nu$,

not come as near to the truth if we regard him with Ennius as one of the founders of Roman prose, and put him in some low degree of comparison with Petrarch, whose diatribes against physicians were no less unmeasured and indiscriminate? Can we be surprised, on looking back to their several epochs, that the harsh puritan and the petulant humanist, the one and the other alike without scientific insight, denounced the parade, the greediness, the luxury, and the glosses of medical adventurers as they saw them? If Petrarch could not understand or foresee the growth of the scientific thought of his own age, shall we blame Cato for that he did not foresee Asclepiades or Galen, nor perceive that in 150 years Rome would be dependent on Greeks not for medicine only, but also for its science and philosophy, and for much of its exquisite and derivative literature? "Belike" Cato, had he foreseen it, might have thought these Danaan gifts dearly bought at the cost of a sterner patriotism, of honour, and of righteousness. However, in all military periods of society-except, perhaps, that of Athens-the craftsman, whether of fine or practical art, has been regarded by the noble warrior with contempt; even schola-leisure itself-in such a period is humble.

It is improbable that Cato, versed as he was in annals and customs, would have accepted the absurd assertion of Pliny that for 600 years Rome had done without physicians, a new-fangled order, and, moreover, a canker in the State. Rome, in all its wars and plagues, must have had more than a domestic medicine, some accredited practitioners, even if of a Homeric order. For example, even in the reign of Numa the Cæsarean operations both for removal of a living child from the dead mother, and conversely, were imposed by law.17 A liability for this service in case of urgency was imposed upon all citizens, it is true1"; but these and other operations, such as the semi-sacred operation of trepanning, those for fractures and dislocations, for fistula, stone, &c., which we know were regularly and successfully undertaken. were no doubt as a rule committed to persons of professed dexterity. We know that there were many Greek physicians in Rome in Sulla's time; and certainly in the first century before Christ the "medicus" was plainly distinguished from the crowd of barbers, quack salvers, and wizards, for in the Digest, L. 13, 1, we read, "Medicorum quoque eadem causa est quae professorum nisi qued justior," and the law goes on to include orderly specialists, as for the eyes, ears, and teeth, for fistula, &c. 19 But "Non tamen si incantavit, si imprecatus est." which are not of the kind of medicine. To do more than note probabilities concerning ancient times of which we have few historical data is otiose; and it is only too certain that in and after Cato's generation many, perhaps most, of the medical adventurers who flocked to Rome were a gang of impostors who stank in the nostrils of high-minded men. Notwithstanding, secluded as early Rome was, it seems impossible that the learned and honourable traditions of the medical schools of Magna Graecia, of Alexandria, of Cnidus, and the rest can have passed over and around Rome, even into distant provinces of the West, such, for example, as Marseilles, &c., and yet left the Mother of Nations—not even then a very simple society—as if they had never been. Pliny was talking of times long before his own, yet he knew enough of Chrysippus, at any rate, to abuse him, and gives his case away when he says: "Non rem (medicinam) antiqui [our ancestors] damnabant, sed artem [the craftsmen]." How can we say there were, and had been, no physicians in Rome before Archagathus, when in the time of Plautus, the contemporary of Cato, we note the Greek cast of his plays, and note specifically such remarks as "Ibo ad medicum atque ibi me toxico morti though we can apprehend Cato's angry repudiations of them. Plautus speaks also of the Roman coin numus (nummus = about 1s.) as being not enough for a doctor's fee (plus jam medico mercede est opus). Again, Amphitryon exclaims, "I have looked for him in the market-place, in the spice shops in medicinis est tonstrinis." 20 There is in Plautus a good deal more of There is in Plautus a good deal more of

17 Compare the old legends of Zeus and Athene, of Bacchus (in Virgil and Ovid), and even of Esculapius, as well as such celebrated cases as those of Fabius and Scipio Africanus.

medicine with a colour so local that it clearly was not a hearsay medicine from Greece. Let us turn, for instance, to the fussy doctor in the Menaechmi-written 200 years before Christ—making his visits and boasting of his grand patients. He appears, moreover, to have had a Home in which he received sick persons for special treatment—"Ad me face uti deferatur. Soin quid facias optumum?" (that is, for a course of hellebore for twenty days). Lucilius again uses many medical words and phrases—not a few, such as cataplasm, &c., taken from the Greek, as if Hippocrates had been filtering in between the generations of Ennius and Lucilius. We note from Plautus also that skin diseases were evidently rife in those days of dirt-Scrpere uti gangraena mala atque herpetica possit.21

Varro (Marcus Terentius) was a full century younger than Cato; he belongs indeed to Cicero's generation, yet he remained a Catonic sort of person; he also was a "summist" of the kind which in Rome Cato initiated, and Celsus, and may we not add Virgil, whose Georgics were written about the same time in Rome, carried to its culmination. In Varro's nine Libri Disciplinarum medicine was the eighth book. In the time of Cicero, who was well versed in medicine, and even in that of Aulus Gellius (Noctes Att., xviii, 10), a knowledge of the broader truths of medicine, and especially of bodily hygiene, was still considered part of the education of a man liber liber-aliterque institutus; smatterings which, in the contemptuous phrase of Galen, had degenerated into "philiatry." In the volume of his output Varro almost equalled Galen; but all is lost, except his De re rustica and a few fragments. He seems, however, to have given to Rome less of medicine than of literature, antiquities, and "natural philosophy," especially mathematics; while to popularise "the higher philosophy" and rhetoric was Cicero's work. However, Varro says much on the salubrity of sites; and Haeser draws attention to the following remarkable passage: When the fleet and army of Pompey were at Corfu a pestilence broke out, and the houses were full of sick persons and corpses. Varro, however, "immisso fenestris novis aquilone, et obstructis pestilentibus, januaque permutata, caeteraque ejus generis diligentia, suos comites ac familiam incolumes reduxit."

While such was the general medical equipment of a Roman gentleman, and while also under the Republic we read of medici rich enough to own slaves, yet the technical practice was chiefly confided to domestic slaves. But we are not to suppose the slave of those times to have been what the haughty Roman took him for, nor to judge him on our prepossessions derived from negro slavery. Roman medical slave was usually a Greek, and his price, by law fixed at not less than 60 minae, was a high one. slavery was a convention enforced by the hardness of the times; the captive was not usually of an inferior race, but in brains as well as in dexterity often superior to his owner. His bondage was an accident; for on manumission his personal qualities often commanded such professional success and independence as to dissipate the sense of gratitude and attachment, and thus to give some check to manumission whereby valuable services were often lost to the patron. Conversely, whatsoever the personal virtues of the slave, the debasing pressure and conventions of that status must have thrown some shade upon his character, so that too often the Greek, by nature slippery and inconstant, as a freedman-and even between the libertus and the Roman there was still a chasm-betrayed himself as a stealthy and venomous rascal.

Of medical colleges and public medical offices I will treat hereafter, but, speaking generally, it is true that in Rome itself there was no kind of professional test or standard to discriminate sharply between such medici as the gentle and accomplished freedman Antonius Musa or the botanist Lenaeus, and villains like Vettius. As manners softened and intelligence and skill compelled recognition the position of these slaves and freedmen improved, especially under the enfranchisements of Julius and Augustus, but their calling

be "manibus puris, capite operto" applies, I fear, rather to religious rites than to antisepsis. The midwife of the clandestine confinement in the Andria of Terence was a drunken slut. I need scarcely direct the reader to Meniere's delightful books on medicine in the Latin Poets,

those of Fablus and Scipio Africanus.

15 In the Lex Regia, "is mater praegnans mortua sit fructus quam primum caute extrahatur."

19 The very word "medicus" itself is of early Italian derivation.

20 Plautus speaks also of interpreters of dreams and omens and of a charmer against disease—"praecantatrix." That the midwife should late allusion to it.

[Nov. 27, 1909. 1571

could not well progress nor gain public recognition as ars prudentiae majoris. Thus it was that, even under the Empire, Roman medicine remained almost wholly Greek, for the few physicians, such as Scribonius Largus, who bore latinised names, were nearly all of them Greeks.²²

How are we, then, to explain the enmity of Cato; and the malice of Pliny who, while he endeavoured to ignore the physicians, could not refrain from signifying by his indiscriminate if not wholly unjustifiable abuse that they existed, and among the "antiqui" had existed, only too abundantly? Now, the fault of these physicians was not so much that they were crafty and rapacious as that their craft and rapacity were not of the Roman sort. As the physicians in Rome were practically all Greeks, their ideas were Greek, so Greek that no Roman could enter into them; furthermore, these Greek notions were not only mischievous in medicine, but in their more general tendency were socially subversive. The scent of a ruling class, secular or ecclesiastic, for inquisitive or esoteric opinions is amazingly keen, and its resentment ruthless. How haughty, ruthless, and unreceptive was the temper of the conquering races in Rome, how sacred were their religion and rites, how rooted their superstitions and folk medicine, how obstinately impermeable their qualities and customs to new ideas, and how incapable of elastic adaptations, we have already seen. We shall not wonder that all these conservative opinions and instincts should have incited, especially in Republican Rome, an alarm against foreign ideas. The old Roman of the type of Cato, austere and imperious as he was, was also, consciously or subconsciously, apprehensive of the instability of his State. Built as it was, not only upon slavery but also upon the quicksand of a restless, excitable plebs, mostly of alien blood, its security could be maintained only by the rigidity of the old iron will, consecrated tradition, military framework, and hardy strenuous habits. Thus the dominant class was clinging fiercely to creeds and rites whose validity they dare not suspect, and to intellectual conventions which, dare not suspect, and & Intellectual conventions which, already sapped by Hellenic curiosity, were ultimately by Christianity to be overthrown. This issue the old Roman dimly but uneasily foresaw. And is it too fanciful to surmise that no less dimly, but by some community of racial instincts, the bent of the subject or plebeian Roman was apt to assimilate the notions of his distant kinsfolk of the Aegean, and to be attended by the fields passions the irresponsible wit and stirred by the fickle passions, the irresponsible wit and faction of that clannish primeval race then, as before and since, intolerant of rank, though submissive to despotism? Such may have been Cato's presages; such, at any rate, was the upshot. For with spoils came luxury; with the deletion of Carthage ease and security; with intellectual curiosity the sapping of creeds and the decay of patriotism. It is scarcely true, I think, to say that Rome was unstable for lack of a middle class; the equestrians took some such place; the instability lay in the rift between the upper classes and the plebs, an unassimilated and naturally turbulent mass, mixed with the nation but not mingled or organised with it.

LECTURE II.

PRESIDENT AND FELLOWS, -As Coleridge said of Greek literature so of Greek medicine, it is "a superfetation upon and not an ingredient in the national character." The first physicians to wend their way to Rome were of those who we know were employed about the gymnasia and the arena.23 But on the common knowledge of the standard histories, the trita scholarum, I will forbear to dwell. Archagathus arrived in Rome about 220 B.C., some 20 years after the Punic war for the cornlands of Sicily. He was one of the first to feel the brunt of Roman indignation at the blasphemy of mistrusting the protecting gods, and at the implety of supplanting the tried resources of the Penates. Was it only this prejudice which turned his title of "Vulnerarius" into that of "Carnifex"? Was he a barbarous surgeon or was this story only Pliny's fun? For, on the other hand, he certainly was accepted as a Roman

citizen, and a taberna was assigned to him at the State expense in the city near the Forum Marcelli. Whether or not he was subsidised as a public physician - δημοσιεύωνafter the Greek fashion is an interesting question, for if so, as we shall see later, this office must in Rome itself, though not in the provinces, have fallen soon into desuetude.

Passing from Archagathus over obscure names and traces, I would concentrate our attention, in respect of the effective invasion of Rome by Greek medicine, upon the great name of Asclepiades. It is one of the flouts of time that the reputation of this great physician had fallen, not only into neglect, but even into obloquy; and the belated duty of restoring his name and place, after the lapse of nearly two thousand years, to their merited honour has been reserved for our own times. I say after nearly two thousand years because, although Asclepiades was born somewhere between 130 and 124 years before Christ, and 30 years later was famous, yet his fame suffered no eclipse until the star of Galen arose; then the torch of Asclepiades was quenched. Never a voluminous writer, his works, scarce by the fourth century, by the sixth century were lost; so that his reputation was at the mercy of any idle scribbler whose malice was thus placed beyond direct confutation. Something like the same neglect befell Celsus, whose treatise on medicine was also practically lost until the fifteenth century, when it was rediscovered, as it is said, by that respectable Pope Nicholas V. The facts according to Sabbadini, are that the first and less correct MS. was found at Siena by the humanist known as Il Panormita; the next and better one came to light soon afterwards in the Ambrosian Library. Portions of Celsus, however, had probably survived also in the obscurity of monkish closets. The work was not printed until 1478, at Florence. It is interesting to us to note that Politian took some pains with the text of Celsus, and that among those who attended his lectures were Grocyn and Linacre. 24 But Celsus was a Roman gentleman and a layman, whose treatise on medicine did not arouse any jealousies, and whose credit was safe with his own coterie. The spiteful arrows of Pliny were shot elsewhere. Neglect, therefore—unmerited neglect—might, and did, overtake Celsus, but not contumely.

It may be that this earthly orb, when it judges, judges securely; but it takes an unconscionable time to consider its judgments, and too often meanwhile this loss of documents arrests the course of its justice. Six hundred years ago, when the path of secular knowledge was the path to persecution or to the stake, flourished, or tried to flourish, Roger Bacon, the friend of Grossetête and Adam Marsh, one of the most masterly spirits of any time or people, and one of the boldest and most unfortunate champions of the emancipation of the human mind. Yet last year the historical school of his own university knew no better than to represent Bacon publicly as a buffoon. So much for humanism. And if this be true of modern history, what may we expect concerning the submerged scientific geniuses of two thousand years ago! Now I will not compare the memorable talents of Asclepiades, whose reputation for something like this interval has been under eclipse, with the genius of Bacon; nor the career of that favourite of kings and harvester of fees with the bitter bread of captivity and the ironical denial of the currency of the pen to the bounty of an un-conquerable mind; yet, had Asclepiades been a smaller man than in fact he was, for the sake of historical truth no inconsiderable measure of justice would still have been his

Asclepiades may remind us in many respects of Boerhaave. In the one case and the other affable manners, good fortune, and worldly success threw a glitter of valgarity over a career of rich practical and philosophic attainments, versatility of mind and temperament, rapid clinical perception, and sagacious insight into the conditions of health and disease; these were the endowments of both men, and in them approached, if they did not quite amount to, original genius. We meet with the curious coincidence that, in his first dissertation, Boerhaave also occupied himself in part with the philosophy of Epicurus. To Boerhaave ingratiating manners, elegant accomplishments, and popular vogue and fortune became no reproach; but in Asclepiades these qualities have been construed into sycophancy, sophistry, chicanery, and avarice. It may be said that

²² Sextius Niger and Julius Bassus, in Cæsar's time, are said to have been Romans, though, as the fashion was, they wrote in Greek.
²³ Aulus Gellius, Noct. Att., xii., 5.

Asclepiades lived a long time ago; that his contemporaries knew him better than we can do; or, anyhow, that there is no use in worrying over dead issues and obsolete reputations. We shall see, however, that Asclepiades occupies not only a high but a cardinal place in the history of medicine. Broken as are the lights in which for us he stands, yet his is the first figure which stands forth under any illumination since the dispersion of the greatest schools of Greece. The great names of Herophilus and Erasistratus are but shadows. Again, in so far as history is, or is to be, a science, or even morally true, no fact is to be taken of its apparent dimen-Now the cardinal moment at which Asclepiades flourished was that of a new outpouring of Greek philosophy and medicine into the alien air of Rome. The meaning of his career contains, therefore, much of the meaning of the age in which he lived, and of which he was a type; and, if the report of his contemporaries were coloured by envy or prejudice, our view of the period and of the course of the history is so far perverted. We must weigh the value of each witness, and compare the witnesses one with another, remembering that calumniare audacter, semper aliquid haeret. Moreover, we must not give too much latitude to the word contemporary.

About 130-124 B.C., then, Asclepiades was born, at that interesting city Prusa, in Bithynia; so that he was about a generation older than Lucretius. His name indicates that his family had some connexion with the medical calling. But the name was no uncommon one; of his time 14 persons are known to have borne it, and it seems the physician, himself an eloquent man, was confounded with another Asclepiades, a rhetorician; whence arose Pliny's spiteful legend that, having found rhetoric unprofitable, Asclepiades had turned to medicine with a sophist's adroitness and the ignorance of a layman. But to rectify our definition of a contemporary, it was about 70 years after the death of Asclepiades that Pliny was born; and the prudent Celsus who lived a little earlier, though none too willing a witness, says of him that "Medendi rationem ex magna parte mutavit." Asclepiades has suffered the more in reputation with modern English scholars as Greenhill, lately the honoured friend of some of us, and in medical history the revered teacher of us all, in my opinion and that of others, accepted too readily the irresponsible invective of Pliny, and the current estimate founded upon his testimony, reinforced by certain strictures of Celsus and Galen which were animated by controversial strife, not by moral censure. With such doctrinal differences, and the schisms which gave rise to them, I will deal presently. Suffice it to say now that for Asclepiades medicine was no afterthought; from his youth he was educated for our profession. In Wellmann's 25 opinion he was not only thus educated at Athens, as we now know, but probably at Alexandria also. It was from Athens that he brought to Rome a theory of medicine founded upon the atomistic philosophy of Democritus, then passing under the name of Epicurus, and soon afterwards to be transfigured in the shining car of Lucretius.

As in England the adverse view of the life and doctrine of Asclepiades received the sanction of Greenhill, it is from him that I must curtly present it. In his wellknown article in Smith, Greenhill says, "Asclepiades may fairly be characterised as a man of natural talents, acquainted with human nature, or rather with human weakness, possessed of considerable shrewdness and address, but with little science or professional skill. He (upon the plan which is so generally found successful by those who are conscious of their own ignorance) by villifying the principles and practice of his predecessors, and by asserting that he had discovered a more compendious and effective mode of treating disease than had been before known to the world. [Italics mine.] ... He directed his attacks more especially against the writings of Hippocrates." Greenhill then proceeds to argue that the methods of Asclepiades owed their popularity to his assiduous attention to everything which contributed to the comfort, flattered the prejudices, and indulged the inclina-tions of the luxurious classes. "We cannot fail," he adds, "to recognise in Asclepiades the prototype of more than one popular physician of modern times." This is tolerably scathing; and I suspect the distinguished critic, who was

At a much later date, some half-a-dozen years ago, a tract by Dr. v. Vilas came into my hands which made a radical alteration in my estimate of Asclepiades. It may be true, as Max Wellmann says, that v. Vilas was not sufficiently equipped with learning to do full justice to his theme; still Wellmann's standard is a high one; and a pioneer such as v. Vilas may on a humbler scale deserve very well of us. He put his points well, and supported them with no inconsiderable information. Moreover, he did the reader the service of putting him in the way to discover the earlier literary testimony. M. Albert also, in his Les Médecins Grecs à Rome, has given a balanced and better informed estimate of the place due to Asclepiades; and Fuchs (in Pagel) and Neuburger (the latter especially, whose work I had failed to consult until this lecture was under correction) have dwelt more adequately on the evidence for a far different interpretation of his character and talents; yet even these authors realise imperfectly the weakness and bias of the persistent detractions. Aliquid haerebat. The last and most convincing vindication of the place of Asclepiades in history is the essay by Wellmann to which I have already referred. Without claiming for Asclepiades a measure of magnanimity far beyond the easy standard of the age in which he lived, we shall remember, nevertheless, the gross licence of backbiting and invective then tolerated, nay, even customary, in Rome. extravagance we see colossal examples in the forensic orations of the time, even in those of men as cultivated and humane as Cicero; and in cases where we have better means of knowing the truth than remain to us in the instance of Asclepiades. Moreover, in the latter days of Athens and Alexandria, Hellenism, settling on its lees, had become more and more artificial and disputatious, more and more charged with schismatic animosities. In these passions of opinion reputations were indiscriminately devastated.

It is narrated of Asclepiades that one day, passing along the street, he saw a body stretched upon a bier, on the way to burial. He interfered, perceived some sign of life in the body, and applied restoratives; the supposed corpse quickened and the man was made whole. The multitude acclaimed Asclepiades as a god—to the annoyance, no doubt, of rival practitioners. This story is used in building up the accusations of charlatanry against the too lucky physician. But we know nothing of the circumstances which led Asclepiades to intervene, nor do we know how he carried himself under the adulation. What we do know is, that to expose the sick and dying on the highways for the chance wisdom of the passers by was an ancient and familiar custom. Moreover, we know, from a passage in Galen, that Asclepiades, as Herophilus before him, had devoted especial attention to the pulse. Another, and I think the only other, evidence alleged for the charlatanry or wily complaisance of the Greek is that in a time of growing luxury he made his therapeutical means also luxurious; that he laid aside coarse and drastic remedies for gentler meansfor regimen, baths, diet, exercises, and so forth; and that he introduced these changes in Rome with the manners of Boerhaave and Mead rather than of Radcliffe and Abernethy. But it seems not to have occurred to historians to consider whether these mitigations of practice were supple concessions to a voluptuous generation, or were consistent with a new and revolutionary doctrine, not of his own invention, but a fountain from the Alexandrian stream of thought, which drew upon him the hostilities and revenges which pursue innovations and innovators. That Asclepiades should have lifted up his voice against the sacred head of Hippocrates has made all historians, from Celsus to Dr. Withington, righteously indignant; and not without some reason. The leader of the Hippocratean school had seen

better versed in medicine than in philosophy, was not indisposed to use this parable of Asclepiades for the chastisement of certain professional vices of his own times. Dr. Withington, who may be said to represent opinion as now prevalent, with a more even verdict but still with an ironical pen, sides, on the whole, with Greenhill. He, too, is not unnaturally angry with Asclepiades for his revolt from Hippocrates. Nevertheless, during the last century there were not a few writers to take a more respectful view of Asclepiades, both as to his virtue and ability. The first scholar to qualify my own estimate of Asclepiades was that brilliant friend of my youth, Maurice Raynaud, snatched so prematurely from his friends and from medical science.

²⁵ Wellmann, Report of Congress, Köln, September, 1908, Münchener Medicinische Wochenschrift, Oct. 15th, 1908.

certain aspects of pathology with the eye of genius; Asclepiades saw another—a smaller side, if you please, but not fictitious. Yet there is no evidence that his opposition to Hippocrates, as construed by the Dogmatists, was embittered by personal acrimony; it seems to have been in the form of argument, and of sarcasm pointed by epigram. It is indeed a little curious that he should have called the Hippocratean expectancy a study upon death (θανάτου μελέτη), seeing that his own movement had been from dashing therapeutics to more rational and temperate methods; but this very discrepancy seems to mark his polemic as petulant rather than impious, while Galen's arrant teleological convictions were outraged by the flippant quip that Nature was as ready to kill a man as to cure him. But in moments of temper have not some of the modernest of us said the like? The fragments of Asclepiades, who is quoted by about thirtythree authors in various fields, in which passages, moreover, ten more references are embedded, were collected by Gumpert in 1794. The chief sources, however, are only four-namely, Celsus, Pliny, Galen, and Caelius Aurelianus; and of these Caelius Aurelianus is the most important. Unfortunately, such has been the ill luck of Asclepiades, that for many generations the writings of Caelius Aurelianus were lost, or concealed under corruptions of his name. By the same misfortune much of our knowledge of Soranus and of the history of the sect of the Methodists lay long in

A modern writer on medical history has made the interesting remark that as celestial bodies, while themselves invisible, may in some measure be recognised by their influences upon the paths of the bodies visible, so phases of the past of which, as in the case of Alexandria, the records are lost, may in some measure come into our ken by certain otherwise unaccountable deviations of recorded We must endeavour, then, to calculate from the orbits of medical thought and practice which we can plot out, those inferences which, in the absence of records, may give us some notion of the history of medicine during the blank period between Hippocrates and Asclepiades; and for a moment I must revert to the geographical aspects of the problem. We have seen that before and during the period which we may briefly call the Homeric the western seaboard of Asia Minor was not Greek; it was an outlying border of an inland power then strong enough to hold it against western encroachment. Miletus, for example, was for the Greeks of that period a city of the "barbarously-speaking Carians; although the Carians were experts in certain delicate arts, yet they spoke a tongue unknown to the Achaeans. Mr. Hogarth thinks that the north-west corner of Asia Minor and Rhodes-Ialysus, Cameirus, &c.-first became Greek. As the inland overlords-probably the Hittites. Aryan invaders from the north, who were not a seagoing people-began to lose grip and shrunk away from the seahoard, the fitful raids of the Ægean people became consolidated into permanent colonies. How these colonies grew into the magnificent cities and intellectual and artistic centres of Ionic Greece—centres which retained their vitality through many vicissitudes down to Byzantine times—there is no need for me to describe. The Alexandrian Empire began about 50 years after the death of Hippocrates, and Alexandria became the centre of trade and intellectual activity; yet Attalid Pergamon was almost comparable with it for culture. The swift advance of Greek science in Alexandria is comparable with the bloom of Greek art in Athens; Euclid, Archimedes, Aristarchus, Hipparchus, Ptolemy, Heron, and other men almost as great, carried the sciences forward, especially astronomy and physics, with astonishing effect, and the great school of medicine sprang up which produced Hero-philus and Erasistratus, to us almost mythical names; so illustrious was their fame, so little are they known Our reasonable hope that the discoveries in modern Egypt would bring forth some records of Alexandrian medicine has so far been disappointed. At the time of the foundation of the school of Alexandria the tradition of Hippocrates was probably in full vigour, a tradition, that is, not so much of formal doctrine as of observation, comparison, and suspension of judgment. For, although it is true that the humoral doctrines were held speculatively, yet the observant reader will perceive in the best Hippocratean treatises how little of the practice was derived | traced the course of some of the glandular ducts.

from a priori applications of them. This pedantry grew up with the Galenists. But we know from this positive medicine, as from religions, how under the Alexandrian mixture of Greek and Oriental tendencies—especially of platonic and pythagorean ideas certain notions, in medicine, the humoral doctrines especially, crystallised out in exaggerated shapes; and how principles and even words becoming detached as abstract dogmas and terms, gained acceptance as forces or as entities. Hence these later traditional teachers became known as λογικόι-dogmatici; medicine became more than ever interfused with philosophy, and probably the Timaeus, as Hauréau said, a bad training ground for ignorant men, began to impose itself upon physiology, as it did in the Middle Ages. To these tendencies were added from the East other influences also, of still worse consequence; motley mysticisms and occultisms, emanations, astrology, and the whole apparatus of demonology. From Pharaonic Egypt medicine probably received little, for good or harm, unless it were the accumulation of drugs; medicine under the Pharaohs was dried and sterile, and the anatomy of the embalmers was as rudimentary and pettifogging as a quartermaster's astronomy.

These extravagances, as was natural, resulted in the empirical reaction to which I shall allude presently. Meanwhile we may turn to the Greek tradition, not purely Hippocratean, but generally speaking almost free from sacerdotalism, on which Herophilus and Erasistratus were nurtured. The formal attempt to contrast the schools of Cos and Cnidus, and to allot to each its several system of argument and practice, fluctuating as such doctrines must with the inclinations of the more eminent leaders, was perhaps never a very profitable inquiry, and in the absence of almost all considerable documentary data it is in the opinion of Haeser impracticable. All we can safely assume is that on the whole the Coans were disposed to have regard rather to the general state of the patient, the equipoise of his functions, and the external conditions, such as climate, whereas the Cnidians were disposed to give more attention to the organ affected, and so to rely more on local than on constitutional means of cure. In our own terms we should say that the Cnidian would have discouraged general pathology, and that reliance in prognosis and Reneral pathology, and that renaines in prognost and therefore the research and Naturae (νόυσων φύσις larpòs) was a Coan point of view. Asclepiades, instructed in the physics of Alexandria, cannot but have recognised the tendency of moving systems to regain equilibrium, and from his practice it is evident that he protested, not against this beneficent bias, but against the teleological way of putting it. And for Aristotle himself, in distinction from Galen, it is no less just to admit that "teleology" meant no more than an analysis of statical relations, that the bodily functions knew no end outside themselves. From allusions in Aretaeus, Galen, Caelius Aurelianus, and other authors we apprehend that at the time of the rise of the school of Alexandria both these earlier schools, Coan and Cnidian, were in activity. The son-in-law of Hippocrates, Polyhus, in magnanimity, sagacity, and experience worthy of his noble kinsman, had carried forward the Coan school with signal success, and we cannot suppose that so eminent a physician as Diocles, though resident at Athens, could have been without considerable influence on the rising Alexandrian school. Diocles was too wise and too experienced a man to be a partisan, yet, as a platonist, his influence may have helped towards this bias in Alexandria; he may have sent them a copy of the Timaeus? Praxagoras of Cos, the first physician to teach the value of the pulse, was the master of Herophilus, who, and whose scholars, were accordingly, with more or less truth, regarded as in habit of mind Coan; while, as Chrysippus the Cnidian was the master of Brasistratus, he and his scholars were reckoned on the side of the tradition of Cnidus. In nearer proximity were the important schools of Magna Graecia and Sicily, of the great disciples of Pythagoras and Empedocles. Herodotus speaks of Cyrene and Rhodes as the two great medical schools of his time. It is probable that the inclination to anatomy was carried into Alexandria by the influence of Diocles and Praxagoras; for, although Galen respectfully banters him on the roughness of his dissections, Diocles was no inconsiderable anatomist. He is best known as the discoverer of the punctum saliens, but he carried the distinction between the venous and arterial areas beyond Aristotle, and

anatomy, like that of Galen, was of animals only; it is the distinction of the Alexandrians, on the advantages peculiar to their city, to have founded the anatomy of man. Unfortunately, too soon afterwards human anatomy-never practicable, perhaps, in Athens—became again impossible, and what had been gained in Alexandria must have been, as physicians are wont to say now of pharmacology and experimental psychology, too far from the sphere of practical medicine to be of cooperative service.

In discussing the later sects, in some of which anatomy was thus repudiated as otiose, we must remember that Daremberg, rather against the impression given us by Galen, was of opinion that up to the time of Asclepiades the school of Erasistratus had prevailed over that of Herophilus; and such also is my opinion, so far as this, at any rate, that the Erasistratids seem to have this, at any rate, that the Masstratus seem to have been commonly accepted as the "progressives" and the Herophilids as conservatives. This point is one of some little importance, as we shall see. It is known that during the life of Asclepiades some of the disciples of Erasistratus founded a medical school at Smyrna; and whether it be true or not that Asclepiades studied in Alexandria, which, in spite of the loss of its political importance on the shift of the centre of political gravity to Rome, was still a seat of cosmopolitan learning, a hive of Romans, Greeks, and Jews, we do know that he began his medical studies in Ionia, where in his time were the great cities and great schools of which I have spoken.

Now, in consequence of intrigues and persecutions in the early Ptolemaic period of Alexandria, many philosophers, physicians, and men of science were exiled or left the city. Certain of the emigrants settled in Asia Minor and founded or developed these medical and other schools in Ionia and Syria; as, for instance, at Laodicea, and so forth. From the earlier of these schools issued many eminent physicians, among them Alexander Philalethes and Cleophantus, who was one of the masters of Asolepiades. From the school of Laodicea came the oculist, Demosthenes Philalethes, whose renown was great in the Middle Ages. Now Cleophantus is mentioned by Pliny himself (N. H., xxvi., 8) as recommending wine as a medicine; an ancient remedy adopted by Asclepiades also, and imputed to him for unrighteousness. The school of Laodicea was founded by followers of Herophilus, so that Themison cannot have been deeply imbued with the doctrines of his birthplace; that of Smyrna, founded by one Hicesius about 50 B.C., when Asclepiades was an old man, was, as I have said, Erasistratean, so that these principles were still flourishing. Now we are told that Erasistratus, after his master Chrysippus of Cnidus, vigorously opposed the abuses of venesections, of purgation, and of emetics and clysters; Cnidian mitigations which in Asclepiades Pliny wrathfully denounced as cajoleries, for how in the face of a disease with horns and hoofs could any honest physician dare to stand prating about "Cito, tuto, et jucunde"—the wellknown formula of Asclepiades! Again, Erasistratus laid stress upon diet, regimen, and exercises; and it is to be noted that he originated that initial abstinence which Asclepiades, and after him the Methodists, made so much of at the commencement of a cure, and which Galen indeed approved. The disciples of Herophilus, on the other hand, as we note also in Galen, were much more addicted to venesection and to a profusion of drugs. Herophilus himself, indeed, seems to have been a somewhat severe practitioner; but he retained the Hippocratic reliance on clinical observation, and was the first physician to watch the pulse and to describe its characters, even with excessive refinement.

By these considerations we are led to the subject of the medical sects. As the medicine of Alexandria stiffened, and was drawn out into naked formulas, there, as under like circumstances elsewhere, a reaction set in, which, however, by a contrary extravagance ended in a similar sterility. Thus, at Alexandria, in the later part of the third century, or, as it is said, a little earlier, under Philinus of Cos, a pupil of Herophilus, arose the sect of the Empirics, whom in a former essay I have called the Philistines of Medicine. Like our own Philistines, these physicians were not without excuse, and were guided by a sort of brutal if rather barren common sense. In discussing the history of schisms and sects we must endeavour not to accentuate the differences by logical oppositions, but to perceive the example, that a patient has naturally curly hair will be modes and impulses which drove men apart. Men rarely irrelevant; and as it is not every man who knows what to

separate for fantastic or empty reasons, nor even on mere divergencies of temperament; they secede because certain relatively enlightened minds begin to apprehend the hollowness or inadequacy of current tenets. They secede and carry others with them; the established party is wroth, the dissenters hit back, and in the fury of their disputes and repartees the points of difference are forced into exorbitant contrasts. While in calmer moments no sensible dogmatist would have admitted that he treated his patents on an abstract formalism, so no sensible empiric would have admitted that he treated them on detached phenomena. without any attempt to attach fact to fact, or to interpret their directions. Yet in these dissensions of Alexandria the dogmatist was represented as recognising no facts, the empiric no reasons. Some such extremists there may have been. Empiricism has, notwithstanding, been a valuable discipline, a more valuable discipline than scepticism, because it bases itself on action, while the sceptic gradually draws aloof from action. Celsus did not lose sight of these considerations of historical justice, but Galen accused the empirics less fairly. From Celsus we gather that the empiric of that day relied on three methods: on chance observations of happy results, but also on deliberate experiments or trials, and on systematic collection of facts. From Menodotus we learn that the empiric accepted what he called an ἐπιλόγισμος—which I might translate as common sense; for instance, we read that in a case of disease of the brain signs of any former injury to the head would be sought for, and weighed, even if outside direct perception. Still in his mistrust of tentative hypothesis the empiric was an extreme Baconian; he believed in induction, but did not apprehend the inductive method in its completeness; indeed, he tried to restrict himself as narrowly as possible to proximate causes, and to regard longer concatenations and remoter causes with suspicion. The faults of the empiric were that he was unaware of the fallacy of enumeratio simplex; he had no criteria; and in treatment he would be guided only by the uppermost signs. Obviously, then, he would vilipend the only anatomy we could know, as Sydenham eschewed pathology. We have surmised that even the anatomy of Alexandria was not developed so far as to give much practical aid to medicine, except in some confirmations of And it is a remarkable tradition concerning surgery. And it is a remarkable tradition concerning Herophilus that this brilliant anatomist did divide his science from his clinical practice, thus leaning towards the empirics; as in later times revolts have been made to clinical observation from an inchoate pathology. Soranus, indeed, said necropsies were useless—"dνατομή (that is, post-mortem examinations) dχρηστὸς ἐστιν." And surely in the midst of Alexandrian visions many of the sayings of the empirics were refreshing; such as these, quoted by Celsus, "Ne agricolam quidem aut gubernatorem disputatione sed usu fieri"; "Morbos non eloquentia sed remediis sanari" ; or even the characteristic "Non interesse quid morbum faciat sed quid tollat." The empiric at worst meant business. And we can readily understand the testimony of Celsus and others that the empirics turned out excellent surgeons, such as Heracleides of Tarentum. They were no transitory sect; we read of professed empirics down to the time of the half empiric and half sceptic Sextus Empiricus in the fifth century. In these times, and before them, we find that the medical like other sceptics, as they lost their zeal, began to crave for coarse mental stimulants and gave themselves up to rank superstitions.

Still, as I have said, the more rational empirics undoubtedly put symptoms in some sort of major and minor subordination, and they esteemed the clinical descriptions of Hippocrates and his immediate followers. Even as physicians they could not ignore the memory of experiences nor assert that observation can proceed without connotation; but assert that to observation can proceed without only but in principle to the $\ell \nu \delta \epsilon i \xi i$; of the dogmatist they opposed rippysis. The best rendering of these terms I have found in Castelli, who renders $\ell \nu \delta \epsilon i \xi i$; as the determination of agents by the causes and mode of generation, indicate ex indicante, and τήρησις as cognitio fide sensum; or, as I may put it, a tight attachment of the perception to the mere events. On this habit Galen, in his treatise on Sects, rightly comments that, as phenomena are infinite, we cannot but select; we cannot but note one feature and discard another-for

accept and what to discard, therefore discerning observation implies training. Moreover, many of the profounder affinities cannot be detected but by reason. This is, of course, the perennial quarrel between the practical man and the theorist; the theorist is prone to overlook the contingent, the practical man to see nothing but the immediately accessible, incidents. Still, even early and rude empiricism could not but begin to demand explanations, and to perceive that there were things άδηλα, as well as φανερά, with which, if true affinities are to be traced out, the understanding must deal. One fact was not as good as another; facts had their relative values, to be appreciated by a mental operation, and some, indeed, were crucial. But, persisted the empiric, clinical observation cannot teach us causes, while shrewdness and insight with experience— $\pi\epsilon i \rho \alpha \tau \rho \iota \beta \iota \kappa \dot{\eta}$ —can by provisional axioms make order enough to give the physician no insufficient guidance in the infinite world of symptoms. The empiric starved his method by isolating it. With these and such limitations, however, it would seem that the empiric, as such, could never have risen even to the bare idea of preventive medicine.

The empiric did not see that the human mind cannot content itself with perpetual suspense, but in default of some chain of reason will betake itself to analogies, which are usually superficial and false; nor did he perceive the indirect influence of the sciences in training the mind as an instrument to accuracy and method. Serapion, indeed, explicitly advocated analogy— ἡ ἀπὸ τοῦ ὁμοίου μετάβασις a method fraught with the gross errors which I have indicated in the history of folk medicine. A debased empiricism must then abut either on the one hand by recognition only of the coarser phenomena upon folk medicine, or on the other, as in Sextus, upon the fatigue of scepticism; but more enlightened empirics, such as Menodotus, came near the salvation of the inductive method, and definitely did take account of remoter and obscurer causes. Menodotus, as M. Favier in an able essay has shown, even recognised the value and purpose of provisional hypothesis. 26
The contrary tendency to scepticism is indicated by such terms, common to both empirics and sceptics, as εγκέρησις—a lighting upon events, as opposed to conceptual anticipations of them. When we try to compare the standpoint of the dogmatist with that of the empiric, we are met on the threshold with the curious question, How much in the direction of the understanding the senses contain, or imply; how much diarbia - or the intelligent collection of apparent facts, contains of λόγισμος—or a reconstruction of them; and again, how far these processes are functionally in combination with toropla or memory? On reflection we shall perceive that only in an abstract logical scheme, in a sort of Athanasian mosaic, is the mind divisible into such severalties. The faculties of mind and body work not in compartments but as a contexture; and in so far as these faculties are drawn asunder the functions of the whole understanding are thrown out of balance and its products perverted. In the school of Hippocrates it is true that humoral hypothesis was professed, yet in the matter of practice the bent of it was strongly empirical, and the understanding was regarded as receptive rather than productive. It was to this attitude of mind that Sydenham returned to a sort of systematic empiricism making for the plotting out of phenomena in series, in some contrast with the compara-tively occult curiosity of Morgagni about seats of disease, and of modern medicine about their genesis. It was in their reliance on sagacity before logic, that the saner dogmatists —such as Celsus—were Hippocratean; they trained and trusted the faculty which Cicero calls ingenium sagax. But, after all, perhaps few schools—as few religions—were as bad as their creeds.

Of the state of medical opinion in Rome in the first century B.C. we have but indirect evidence, and even of this not much. Moreover, we have to set aside the random invectives of Pliny; happily, indeed, we are able to discard them for the evidence of Celsus, a sober and competent author, who, moreover, flourished nearer to the time we are considering—the time, that is, of the setting of the school of Alexandria and of the large migration of medicine to Rome. In the treatise of Celsus, then, medicine in Rome is presented to us as still in its main quality solidly Hippocratic, fortified by Alexandrian science, and chastened by the

influence of the empirics who were protesting against the later Hellenistic vagaries in Oriental metaphysics. As I have recently published a note on Celsus in the Classical Review, I will not stop to repeat it here; I will do no more than indicate that among the upper classes of Rome in the first century B.C. medicine had been lifted far above the folk medicine of Cato, although beneath these classes it was flowing on in scarcely diminished volume. was floating upon a Græco-Roman aristocracy of family and wealth a Greek, but still, as represented by their spokesman Celsus, a sedate and instructed medicine worthy of the Roman gravity; when, from more than one quarter, burst forth a new and revolutionary idea, cham-pioned by men of great ability, by a poet of transcendent genius, and by a physician rich in talents, which shook the Hippocratean raft almost to pieces. Indeed, in its later and corrupted form it was decomposing the science and art of medicine into empty conceits, when the more tremendous and, on the whole, more virtuous arm of Galen attacked and demolished it. So close have been the alliances between medicine and philosophy one may wonder that the atomism of the unrivalled twin masters Democritus and Leucippus had not made an earlier prize of our art—an art drifting then and since through many ages with uncharted methods, and without anchorages in substantial knowledge; for humoralism had ignored or neglected the pathology of the solids of the body. The triumph of Methodism proved but a hollow show, though, as I have stated upon the elucida-tions of Daremberg, Diels, and Wellmann, its survival, from its beginning to its fading away in Salerno, was a longer story than is usually told. For my part, however, I should speak, not so much of the late survival of Methodism as of its relics, and of these rather as its accidents than as its substance; but it is true that doctrines have their roots deeper in the past, and their vitality lingers longer than is obvious to the cursory observer.

The Hippoeratic Canon is permeated by many inconsistent strains of thought; as, for example, in the Περι διάιτης; the Περι φύσιος ἀνθρώπου; the Περι φυσῶν, &c. Again, Diocles seems to have been a forerunner of the pneumatists. So among the adumbrations of Methodism, we find that Asclepiades apparently held the strange opinion, excusably derided by Galen, that the wrine was not, as Hippocrates ($\Pi \epsilon \rho l$ $\delta \sigma \tau \ell \omega \nu$ $\phi \psi \sigma \iota \sigma s$) truly held, a stream secreted by the kidneys and trickling as rivulets by way of the ureters into the reservoir of the bladder, but that the corporeal fluids rising in vapour exhaled, and, vaguely permeating the pores of the body, condensed in the bladder. Now it luckily happens that Galen, in contesting this very unanatomical but very methodistical notion, remarked that it was in origin pre-Alexandrian. Furthermore, certain opinions concerning plethora, similar to those of Asclepiades, were also held before Erasistratus by one Aegimius of Elis. Aegimius, as it seems from Celsus and Galen, did not accept the humoral pathology, and was therefore neither Coan nor Cnidian in doctrine. Aegimius then may have been the first champion of atomism in medicine, as Asclepiades was really the last. These and such questions are very ably treated by Wellmann in the new Pauly,²⁷ where he traces back the atomistic stage of medical history to Erasistratus and beyond him. Diels is now of opinion that Erasistratus endeavoured to harmonise the materialism of Democritus with the ideas of Aristotle; that, according to Erasistratus, it was by an atomic mechanism that the great artist Nature created and acted, as Galen put it (De Faoult. Nat., II., 2, &c.), "προνοητικήν τοῦ ζωου και τεχνικὴν αὐτὸς ὁ Ἑρίστρατος ὑπέθετο τὴν φύσιν." Health accordingly consisted in a συμμετρία (rhythmical system) of these rudiments.

Again, as we learn from Brieger and other commentators, Democritus opined that the soul consisted in a collective activity of spiritualised—that is the finest—atoms in all parts of the body; this opinion was held with a small difference by Asclepiades also, who proceeded to found upon it a positive method of psychiatry, wherein παραφροσύνηwhich he clearly distinguished from the cerebral symptoms of other diseases—was to be treated as a disorder of the brain, a corporeal disease remediable by corporeal means, in which, however, he included music and other psychical influences; a true, and for that age admirable, conception which may be said to have fallen into utter neglect until its

²⁶ Un médecin grec du IIme siècle A.D., Thèse de Paris, On Fragments of this Physician's Writings in a Latin rendering of Galen's De Subfiguratione Empirici.

restoration by Pinel. A note of the rare insight of Asclepiades is to be marked in his ideas of the integration of soul and body; for that these were real thoughts of his, not notions coloured after our modern patterns, is illustrated by such reflections as this—that hallucinations dissolve or diminish in the daytime, because they are counteracted by the data of the senses; as in the rays of the sun a torch becomes invisible. But in the dark the veil of oppression over the senses cannot be drawn away, and thus in sleep, the senses being closed, the pictures of fancy have free play (Cf. Lucretius,

It was then to the remarkable opinions of Democritus on the nature of the soul that Asclepiades, surpassing certain shortcomings of later thinkers, indeed, of Epicurus himself, returned; but now we come to an important advance of his own. Democritus, as I have said, held the interesting view that the soul consisted in the sum of functions, in a cooperation of the atoms of all parts of the bodily system (συγγυμνασία $\tau \hat{\omega} \nu$ alognotian), so that between animation, consciousness, and thought—the άλογον and the λογιστικόν—there were for him only degrees, no radical division. Erasistratus accepted the familiar divisions between the vital principle in the viscera, that of the animal life in the arteries and respiration (τὸ ζωτικόν), and that of the mind (τὸ ψυχικόν). For Diocles the soul was in the blood, for Praxagoras in the heart. It was the corollary of Epicurus that for the sake of the soul the body must therefore be cherished, which led to the degradations of hedonism. Now it is recorded of Asclepiades that in this part of physiology he made certain proofs by experiment. The view of Democritus— $\pi \nu \epsilon \hat{\nu} \mu a$ παντί τὰ σώματι παρακείμενον—obviously excluded a particular seat of the soul; yet, said Asclepiades, in the synthesis the brain must take a predominant part; for he had observed diseases of the brain to be followed by notable perversions of the mind. It was to throw light on this dilemma that he undertook the experiments, in some prescience of the methods of Galen; he decapitated animals of different orders, eels, tortoises, goats, crickets, flies, and pointed out that, though under this dismemberment they could all survive awhile, it was in very various degrees. Moreover, in his research Asclepiades took heed of a certain reserve akin to the system of controls in our experimental method. He pointed out that the functional products were continually variable, even of the soul; this he explained by the incessant whirling restlessness of the atoms (κίνησιs, φόρα, ρυσίs); he warned the empirics that therefore two and more observations could never be made under identical conditions. If, then, Asclepiades, in concentrating his explanation of insanity upon the brain, conjectured that the atoms of the brain were rounder and smoother, and so more mobile, than those in the rest of the body, where they united by hooks to form a web $(\sigma v \mu \pi \lambda o \kappa \eta,$ complexio), yet he was led into this transcendental speculation by observation and experiment. We know, also, that he made post-mortem examinations, for in a gibe of Galen's, Asclepiades, who consistently with his theory and with the teaching of Erasistratus regarded digestion as a merely mechanical grinding and pulping, is derided for not observing different qualities in the digested food, whether in the vomit or "ενταῖς ἀνατόμαῖς." But I will not attempt to detain you by farther illustration of the researches of Asclepiades, for, as in the case of Francis Bacon, his meditations were often more fruitful than his applications. Thus it was his logic which dictated to him that the finest atoms must be in the centre of gravity of the body -namely, in the breast; and, with more truth, he adhered to the belief that respiration consisted in the affinity of these finest atoms for the like finest particles of the atmosphere, those nearest like fire or pneuma, or, as we might sphere, those hearest has the of pheams, of, as we might say, of oxygen. The directions of the $\phi \delta \rho \alpha \iota$ —the atomic orbits—he explained partly by "logic," yet also (as we might expect from an Alexandrian student) by some mathematical conceptions. For this reason the hypotheses of Asclepiades have been seriously compared with those of the iatro-physicists or iatro-mathematicians of the seventeenth century; but surely this is to forget that in the vast interval the bases of the medical sciences had been wholly transformed. Of philosophy the bases continued to be more uniform; Asclepiades, like his intellectual ancestor Democritus, was as convinced a teacher as Locke of the relativity of knowledge and of the relative finality of the appreciations of the senses. Ultimate substance is

άδηλον, and we cannot, he says, carry the bases of our knowledge beyond phenomena (φαινόμενα). 2-3

From considerations such as these, by a closer and wider

investigation of such fragments and allusions as are extant, we begin to perceive that to regard Asclepiades as a smoothtongued and covetous intriguer, bent on plausible inventions and pliable therapeutics wherewith to tickle the fancy of an enervated and self-indulgent society, was an unfair and mistaken judgment. On the contrary, we have seen that this eminent man was educated from his youth for the medical career; that to this end he studied in Erasistratean schools, perhaps in Alexandria itself, and came to Rome inspired by no time-serving, extemporal, or individual sentiments, but by a large and revolutionary system of doctrine seriously intended to overthrow the post-Hippocratean dogmatism, already combated by the empirics. This system, adapted from the atomic theory of Democritus and Epicurus, and developed in its applications to medical science, had been delivered to him through four or five generations of authoritative teachers; and about the same time this theory and interpretation of life, already for two or three generations propagated in Rome, was to reach its zenith in the splendour of the epic of Lucretius. In common life educated men, and even the general public also, were repudiating the crude tenets and the barbarous practices of the old-fashioned medicine; while in respect of the empirics, on the other hand, intellectual observers such as Crassus the orator, 20 Cicero, Atticus, Marc Antony, some of whom are recorded as personal friends and patients of Asclepiades, could not fail to discern the aridity of doctrines which professed to see facts only one by Thus the minds of thoughtful Romans were open to consider almost any plausible doctrine of causation, and meanwhile to welcome more temperate therapeutical methods. At this time it was that Asclepiades arrived from Athens, animated by the atomic theory, a physical conception of nature which in philosophy and literature also had already inspired other eager spirits with the ardour of revelation. and professing to found a new practice upon those methods of diet, active and passive exercises, baths, and the conduct of life which we honourably distinguish as physiological, and that Asclepiades was no ineffectual sophist, but expert enough with his hands on occasion, we infer from his reputation as a surgeon and from the attribution to him of the operation of laryngotomy.

But what about the ungenerous denunciations of Hippocrates? Why, we shall step out of the study, and apply to these scoffs a little worldly common sense. Asclepiades came to Rome as a rebel; he had to fight for his hand against a powerful array of conservative forces, especially against a jealous and none too scrupulous body of practitioners, all or nearly all of them either dogmatists or pretenders, both of which parties armed themselves alike with weapons from the armoury of the older tradition. As for our fathers, Moses being interpreted meant Bishop Usher, so in the mouths of the Greek doctors in possession "Hippocrates" meant the prevalent dogmatics and routine. And it were no inconsistency of temperament in a reformer one day as irascible man to throw controversial missiles at the effigy of a Hippocrates or a Moses, and on the next as sage to treat their persons with reverence. The remonstrances of Asclepiades were far away from the raw and insolent abuse of Thessalus, such as that the aphorisms of Hippocrates were all lies. Pliny is the only writer to impute moral delinquency to Asclepiades; the medical botanist and folk-lorist and the philosophical physician were irreconcilable. Varro, whose leanings were towards the Empirics, bitterly opposed the Epicureans, and in this sense only opposed Asclepiades. Scribonius Largus protested, but with great respect, against a physician who discouraged the liberal use of drugs. The wise and learned Celsus, in a period when literary acknowledgments were usually disregarded, mentions Asclepiades, so I have computed from the index of Dr. Friebos, no less than 29 times; if often with dissent, yet always with respect, and many times with honour—for instance, as "auctor summus" and as one who "medendi

²⁸ For the discussion of these materials derived from Sextus Empiricus, Caelius Aurelianus, Galen, Aetius, Cassius the latrosophist, Antiochus of Ascalon, &c., I am indebted chiefly to Daremberg, Brieger, and Wellmann.

29 Ciccro, in writing to Crassus of Asclepiades as both friend and physician (apparently of both?), says that Asc'epiades was indeed cloquent, adding: "In eo ipso quod ornate dicebat medicinae facilitate utebatur non cloquentiae."—De Orct, I., 14.

rationem ex magna parte mutavit." How paramount in his own day was the reputation of Asclepiades we know from the attempts by other potentates, especially by Mithridates, to allure him elsewhere. Galen, though more acrimonious in dispute than Celsus, yet likewise betrays in his argument, and indeed avows, that the fame and ascendency of Asclepiades were still paramount and that he sought to discredit that fame not in morals but in doctrine. Between such antagonists there could be no truce; and, as Asclepiades had been in his grave for a century and a half, the illustrious Galen got all his own way in the wrangle. Still I repeat that these angry protests of Galen, for much of which there was controversial justification, were a tribute to the authority of Asclepiades, and carried with them no more imputation of guile or dishonour than in the case of Menodotus and others whom he pursued with the same pugnacious eloquence.

While Asclepiades erred towards a dissipation of the specific in the universal, Galen, who belonged rather to the Herophilean tradition, became accordingly engaged and even entangled in too assiduous an occupation with specifics and the consequent enormous polypharmacy. Moreover, Galen had adopted the monotheism which, as it were in reaction from the invasion of demonology, had arisen in Alexandria, and in with it he had woven a highly elaborated teleology, which virtually postponed the divine to the human intelligence and turned any incidental result of the co-adaptation of an organism and its conditions into its end. Besides his loyal devotion to the name and school of Hippocrates, Galen was himself an ardent, only too ardent, humoralist. He relied also upon the Critical Days, repudiated by the atomist school, which, if a remnant of magical numbers, was accented, and more rationally, by the periods of pneumonia—a malady then frequent, and of the malarial influence which tainted many of the other diseases of the Mediterranean. It is a mistake, however, to suppose from this that the Methodists did not recognise crisis; what they denied was that crises were determined by calculable periods.

The researches of Maxwell, Kelvin, and J. J. Thomsonto mention but a few recent workers in this field-have linked us so much more intimately with the atomists of old, that we read even the esoteric Timaeus with less sense of the bizarre; still, for medicine the doctrines of Asclepiades, and still more justly those of Themison and formal Methodism, were very crude, even as hypotheses, and from the peculiar needs of medicine they rambled far away. What the art of medicine needed above all things was positive methods and a ruthless fidelity to facts. I have been led to imply that for medicine even the cramped and illiberal notions of the empirics were less unwholesome than the fascinating and philosophically interesting visions of atomism. Philosophy is one thing, a craft is another, and a craft must walk before it can fly. Atomism did, it is true, recall men to the forgotten solids of the body, yet so very impalpably that not professional antagonists only, but the very nature of things warred against Asclepiades. If the despotism of Galenic tradition became an incubus to medicine, we may surmise that a tyranny of Methodism might have been a worse mis-Methodism would have started indeed with a fortune. "cito et jucunde," and the western sick might have been spared the flourishes of the actual cautery and volumes of blood, but the following centuries were rough; perhaps they were fascinated by rough handling, at least they did not resent it; and if Methodism ignored the vis medicatrix Naturae, Galenism too often forgot it.

To move onwards from Asclepiades; the early atomists had said little of the spatial relations of the atoms, of pores between them.30 Plato supposed his triangles to act in a plenum.²¹ Erasistratus and Asclepiades, however, laid stress on the pores; for instance, if there were no pores in the skin how could one sweat? 22 And Themison, who is commonly regarded, perhaps conveniently, as the founder of Methodism proper, for the pores almost forgot the

atoms themselves. In what kind of association, then, did the atoms seem to the atomists? Had they any conception-to use our current terms-of a grouping of the indivisible atoms into molecules? Even when we come down to Asclepiades, had he in his mind's eye any functional, differential, or heterogeneous segregation of atoms? After some rummage among texts and com-mentaries I have come to the conclusion that to this question no answer can be given. The difficulty is not so much that in respect of a building of atoms into molecules there is no allusion, as that in the relevant passages of the textsfragmentary as they are—the extant terms and sentences are at variance, or indeed contradictory. Some Epicureans, using the word arouos, regarded these particles as ultimate; others, using the word bykos, as divisible; but it is not apparent that any point of constructional principle depended upon the difference. The probability is that the notion of systems of atoms or of compound atoms, as molecules, did not present itself formally to the ancient thinkers as a mode of functional development. They supposed that atoms might stick or crowd together, but they looked upon such adhesions as incidental, and usually, as hampering them in their orbits, mischievous. But Asclepiades, as we have seen, conceived of the atoms themselves as coarser and finer and so differential in function. To read more into their expressions -at any rate, into their extant phrases-is, I think, to import

into them ideas of our own. What is, then, the distinction which separates Asclepiades from Themison—the Epicurean from the Methodist? Well, this—that from regarding the atoms as in a plenum, or, again, as rushing, spinning, or whirling in space or spaces, Themison, as I have said, almost forgot the atoms in the pores, or rather forgot both in the meagre notions of relaxation (ρυσις, τὸ ρύωδες) and constriction (στέγνωσις, τὸ στέγνον) in this area or in that. Asclepiades conceived of the atoms as losing their balance and crowding together in this direction or in that so as to cause a stoppage ($\xi\mu\phi\rho\alpha\xi\iota s$), or at least a retardation (στάσις), of the currents in one part with a corresponding rarefaction in other parts. Of the rarefactions, Asclepiades says less than Themison, for whom they loomed larger, and Themison contrasted the rarefied parts, where he regarded the tissues as relaxed, with the congested parts where they became choked or constricted. Thus, pain for Asclepiades consisted more particularly in a sense of stoppage, of aggregation of coarser atoms-as in thick blood for instance; Themison reduced it to a mere strictum; and in their respective explanations of fever there were the same differences. Generally speaking, for the Methodist acute disease was a status strictus, chronic disease a status laxus. 33 For pain, then, Asclepiades conceded that venesection, preferably local, might fairly be practised, though cautiously and only for instant relief; for he affirmed that on the whole bleeding tended to draw off the finer, the more vital, atoms first, leaving the coarser behind; so that rigor, due to such a peripheral viscosity, might follow venesection. Again, when arrests took place in certain parts, as in glands or in a lesion of a limb, the swift atoms, finding themselves thwarted in their orbits, would sweep upwards from the block, or perhaps from a more universal closure of the pores of the system, and thus set up general fever.

I may digress not inconveniently here to say that the interpretation of fever was one of the great questions of the schools; that of the atomists we have noted. Diocles held that fever was a contingent effect (ἐπιγέννημα) of some morbid process, and Galen took a similar view of it, the not irrational view-over-emphasised in later times by Broussais-that all fever depended upon some focus of inflammation, especially if pus were forming. schools attributed fever to plethora: the Hippocrateans to bile-the degrees of malaria, for instance, being degrees or kinds of biliary crasis. And external poisons were not forgotten-such as bad food or bad gases; for to some such agency Thucydides tells us the great plague of Athens was attributed. By the Methodists, however, these doubts and conjectures were all diluted into the vague conceit of a mere strictum, more jejune

³⁰ Empedocles supposed the emanations from external bodies passed through pores into the organs of sense

through pores into the organs of sense.

If the $\pi\nu\kappa\nu\omega\sigma$ is and $d\rho al\omega\sigma$ is of Anaximenes were not spatial relations of atoms but extenuation and condensation of a uniform "air." For the extant sources the reader is referred to the collection of Ritter and Prelier.

If may here recall the contemporary, and especially methodist, idea of respiration by the skin in man.

²³ That Asclepiades, or any other one physician, propounded the distinction between Acute and Chronic Disease 1 can hardly admit. The prevailing notion in the time of Hippocrates seems to have been that Chronic Disease was a sequel of Acute, and this notion became modified

even than the Asclepiadean stoppages of the pores. This was one of the universals (κουνότητες) of the Methodists; This the other two chief communitates being the "laxum" and a third or mixed state, $\mu\epsilon\mu l\gamma\mu\epsilon\nu\nu\nu$; this last being one of those shifts for the disposal of awkward instances to which most system-mongers are driven, only to find that it unites the difficulties of both extremes. This "mixtum" was inserted by Themison. On those universals Soranus wrote a book, lost with the rest of his works. Thus, conceptions which in Asclepiades were an endeavour to range biology with the positive sciences, to bring medicine into contact with physical methods, to anticipate Heller by bringing the solids of the body into the reckoning, were, by the extravagancies and fantasies of his immediate successors, the Methodists, attenuated into the flimsiest of cobwebs. To the most eviscerated of these notions the Methodists referred all phenomena; they scorned axiomata media, and sought to know the whole without knowledge of the parts. For them the problem of diagnosis was not, what are the phenomena? but how far could the malady be evaporated into a communitas—a strictum, or a laxum, or a mixtum? The treatment, accordingly the strictum of the strictum of the strictum of the strictum of the strictum. ingly, was just a correlative formula—laxative, tonic, tono-laxative—a facile device which, at any rate, discouraged polypharmacy. But, as Galen happily retorted upon them, as Humanity, for example, is a universal, but in the examination of individual cases, or even in inquiring into the species and sorts of Man, one very vaguely useful, so in disease the physician must not only pay regard to particular symptoms and characters, but must also inquire into what Galen called the procatarctic (occasional) causes, such as climate, age, sex, habit, and the like. This aspect of causation was familiar to Asclepiades, who taught, for instance, that diseases behaved differently, and patients tolerated treatment differently in Rome and in the Levant. However, too often these discussions were, after all, fights between one windmill and another. It is curious that each in his own extreme, the Empiric and the Methodist alike, the Empiric glued to his particular, and the Methodist blown into his universal, dispensed with the need of inquiry into causes, or, indeed, into processes. While for the Methodist the specific fact was as soon as possible to be sublimed into one of the three universals, for the Empiric it was an ultimate; the one refused to see it, the other refused to pursue it. This was a sad falling-off from Erasistratus, who made some necropsies; he observed, for example, that in ascites the liver might be of stony hardness. But the Methodists soon discovered—or it was discovered for them that to reduce medicine to two, or even to three, abstract categories was because of its very facility to reduce it to a vapid and fruitless pretence; they formulated, therefore, other universals subordinate to the chief triad. Yet even then, for the explanation of poisoning, of the invasion of foreign bodies, of tumours, and of surgery in general, the idea was unworkable; and, at any rate, in its emptiness of content,

The parallel categories to which their therapeutics were necessarily reduced were of contraria contrariis; if, as in the first stage of fever, there was constriction, then relaxants were to be used; if, as in the second stage, there was solution, then astringents. So, again, in presumptive local leaks or stoppages astringent or solvent remedies respectively were to be directed to the affected area. It is easy to see how such rules-of-thumb must lead, as in fact they did, to the vainest and most senseless routine, and how destructive they were of the method of Hippocrates, which, as Celsus wrote, was mederi oportere et communia et propria intuentem. Still, as in all such revolts, the leaders, as we have glimpses of them down the centuries in Oribasius, Aetius, Alexander of Tralles, were better than their followers. But I must permit myself again to commend the excellent and permanently influential side of their therapeutics derived from their forefathers, Asclepiades and Erasistratus, that which congruently with their physical views led to the correspondent extension and development of the physical means of cure-of passive movements, graduated exercises, special baths, diet, regimen, and so forth. These were the methods which, in the hands of Asclepiades, supplemented the barbarous practices of Archagathus. A proverbial rule of the Methodists, which we trace back to Asclepiades and Erasistratus, was the well-known three days' abstinence with which they commenced the treatment in acute disease.

It was in the later stages that wine and good feeding were recommended.

In obstetrics the Methodists attained distinction, especially in the person of Soranus, whose fame, and the fragments and titles of whose works, testify to remarkable abilities, not in obstetrics only, but over the whole sphere of medicine. The man is reflected in his terse, lucid, shrewd, and practical style. Soranus was, as it were, re-constructed from these relics by Reinhold Dietz, of Königsberg, another learned physician carried off prematurely by death. The development of obstetrics probably arose out of the Alexandrian anatomy; we know that Herophilus wrote upon the subject. Thessalus of Tralles, on the contrary, in the reign of Nero, reveals himself to us as an arrogant boaster, and not only as vainglorious, but as the captain of troops of pretenders, to whom he promised for a fee to teach in six months all that need be known in medicine. Such medicine as Thessalus had to teach might have been written on the proverbial half-sheet of notepaper, and learnt for less money in as many hours. He vaunted himself as the foe of doctors, and on his ostentatious tomb in the Appian Way inscribed himself as Iatronikes. He vanquished, it is true, whatever there was in the science and art of medicine, of understanding, of skill, of patience, and of honour; and must have revealed to the respectable Methodists how near are the boundaries of vanity of doctrine and vanity of conduct. Asclepiades was the forerunner of the Methodists it is true, but it was by Themison and his school that the atomistic conceptions, which at best lent themselves too readily to fantasy, were so reduced, both in theory and practice, to summary forms as to be comprehensible by any illiterate charlatan.

A COMPARISON BETWEEN THE ANTI-SEPTIC AND ASEPTIC METHODS OF OPERATION, WITH SPECIAL REFERENCE TO THE OCCURRENCE OF SUPPURATION.

BASED UPON THE RESULTS OBTAINED AT ST. GEORGE'S HOSPITAL DURING THE YEARS 1906 AND 1908 RESPECTIVELY.

BY H. S. PENDLEBURY, M.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO-ROAD, S.E.;

AND

IVOR BACK, M.A., M.B., B.C. CANTAB., F.R.C.S. ENG., SURGICAL REGISTRAR, ST. GEORGE'S HOSPITAL.

During the year 1907 the use of antiseptic solutions at operations was superseded at St. George's Hospital by the more modern aseptic method. Up to the end of 1906 everything connected with an operation at St. George's Hospital was sterilised by means of antiseptic solutions. The trays and other utensils were cleaned by washing in hot soap and water and antiseptic lotions. The instruments were boiled and subsequently put in a 1 in 60 solution of carbolic acid. The swabs were subjected to a similar treatment, as were the towels by which the field of operation was surrounded. Gloves were hardly worn in any instance.

Dr. O. Slater writes us as follows: "The principal changes that have been introduced are largely concerned with details of technique involved in the substitution of aseptic for antiseptic methods—details which are well known to surgeons and about which it is unnecessary to say anything—and certain changes due to the installation of a more complete sterilising plant than that which existed before the period considered.

I. A battery of sterilisers has been provided, in a room adjacent to the theatres, which are heated by steam, and provide for easy and rapid sterilisation at 100°C. The most important of these is a large double tank, in each compartment of which the whole of the vessels required for an operation (instrument trays, receivers, &c.) can be sterilised at one time. These vessels are all packed into a perforated

metal receiver which is plunged into the steriliser, and after the requisite boiling is lifted out by means of a travelling crane, drained for a moment or two, and then dropped on to a trolley, covered with a sterile towel, and wheeled into the operating theatre. This method has replaced the simple washing out of the vessels with hot water (not boiling) and is rendered so easy by the mechanical arrangements that there is no tendency for those in charge to shirk the work.

II. A supply of sterile water has been provided for the theatres and for the sterilising room. The supply is drawn from the ordinary hot-water supply of the hospital, which has been shown by repeated examination to be sterile, and is cooled by passing through a metal worm immersed in a cylinder through which the whole of the cold water used in the theatres for all purposes passes. Beyond the initial cost, which was small, there is no expense involved for maintenance and little for renewals, while the quantity of water available is practically unlimited.

III. There has been an alteration in the method (formerly very faulty) of preparing and storing sterile salt solution, and provision has been made for the bacteriological super-

vision of this easily contaminated fluid.

IV. The most important change has been in the installation of a high-pressure steam steriliser of sufficient capacity to deal with sterilisation of all dressings, coats, towels, &c., for the theatre and for dressings for the wards. The methods used have been shown by experiment to secure the destruction of highly resistant spores placed in the least permeable of dressings in the centre of the boxes. The boxes are sterilised when closed and no internal cages are used. This saves much space and avoids many risks of contamination. These results cannot, however, be obtained in the ordinary metal sterilising box. The boxes employed have openings about 3 inches in diameter cut in the lid and bottom of the box, and these openings are protected by double gratings of coarse wire between which pads of wool and gauze can be placed. These pads can be easily renewed when necessary. The steam penetrates easily to the interior of the dressings, and there is no difficulty in securing that they are reasonably dry after sterilisation.

Associated with these changes there have been alterations in the nurses' costumes and regulations as to the wearing of gloves and the use of other precautions to secure asepsis. Rubber gloves are now worn by nearly all the surgeons; and many use some form of head-gear. The standard solution in use for the sterilisation of the hands was a 1 in 2000 solution of mercuric potassium iodide and 1 in 500 solution of the same salt in spirit. This is still employed for the preliminary cleansing of the hands, previous to putting on the rubber gloves. The only particular in which no change has been made is in the preliminary preparation of the patient's skin. The field of operation is first thoroughly washed with soap and a brush, next rubbed over with ether to remove any sebaceous débris and fatty material, and finally swabbed with a 1 in 500 solution of mercuric potassium iodide in spirit. A carbolic compress 1-80 is then bandaged on. In the theatre before operation the skin is again cleansed with ether soap and a solution of 1 in 500 biniodide in spirit.

These changes were begun early in 1907 and perfected towards the end of the year. It occurred to us, therefore, that it would be a matter of some interest to publish the results obtained during 1906, the last year of the old régime, with those of 1908, the first year in which the new method was used systematically. For this purpose we have examined the hospital records and have gone into the after-history of every major operation performed during those two years. We should state that at St. George's Hospital the initial notes of every case are taken by the registrar, while the continuation notes are written by the house surgeon in charge of the case, and thus we are forced to rely upon the data supplied by a large number of observers. In compiling these statistics we therefore made it a rule to include no case as free from suppuration unless there was a definite statement in the notes that the wound had healed by first intention or words to that effect. We have, however, in our capacities as surgeon and surgical registrar, personally observed more than half the cases during their stay in hospital, and further, we have been assisted in this inquiry by three of the house surgeons who were responsible for the care of many of the cases that we ourselves did not see. Any case in which the slightest doubt existed was immediately discarded.

Certain classes of cases were also eliminated as being unsuitable for the purposes of this inquiry. These were: (1) abscesses and cases already septic before operation; (2) operations upon the ear, nose, and throat; (3) operations upon mucous surfaces, e.g., upon the rectum and mouth; and (4) cases of appendicitis in which there was already abscess formation or peritonitis at the time of operation. Our reasons for excluding classes (1) and (4) are too obvious to need stating. With regard to classes (2) and (3), it need hardly be said that suppuration can and does occur, but we have excluded them because, while in some suppuration can hardly be avoided, in others it may escape the observation of even an intelligent house officer.

1360 operations are recorded in 1906, and 1180 in 1908. Of these, after the process of exclusion on the lines laid down, only 738 were available for our purposes in the former year, and 673 in the latter year.

The statistics of the two years are given in tabular form :-

								1908.
Total available operations			•••		•••	738	•••	673
Healed aseptically	•••	• • • •				638	•••	624
Became septic	•••		•••			100		49
Percentage of septic cases		•••	•••	•••	•••	13.5	•••	7.2

These numbers are not as large as we could wish, but they are, at any rate, too large to admit of the argument that the improvement is a coincidence. We would point out also that the operators were the same in the two years.

We have further made separate statistics of the results of operations on certain special diseases, and again we give the results in tabular form:—

I.—Radical Cure of Hernia. 1906. 1908. Total cases 188 198 Healed aseptically 162 179	IV.—Operations upon the Mal Genital Organs, Hydrocele, Vari coccle, Relatined Testis, Tumour of the Testis, &c.
,	1906. 1908
Became septic 26 19	Total cases 49 46
Percentage of septic cases 13.8 9.6	Healed aseptically 42 43
II.—Operations on Breast.	Became septic 7 3
Total cases 57 41 Healed aseptically 52 36	Percentage of septic cases 14.3 6.5
Became septic 5 5	
Percentage of septic cases 8.7 12.2	V.—Operations for Quiescent Appendicitis.
III.—Operations on Thyroid	Total cases 65 90
Total cases 13 16	Healed aseptically 59 87
Healed aseptically 12 15	Became septic 6 3
Became septic 1 1 Percentage of septic cases 7.7 6.2	Percentage of septic cases 9.2 3.3

It will be seen from these tables that, as in the case of the total number of operations, the percentage figures are better in all cases in 1908 than in 1906, with the single exception of operations upon the breast. In some of the published statistics dealing with this question, operations in the neighbourhood of the scrotum, such as hydrocele and varicocele, have been omitted on account of the admitted difficulty of rendering and keeping the field of operation asceptic. It will be seen that in this inquiry we have made no such exception. In no case did the septic infection prove fatal nor did it materially prolong convalescence. For instance, in those cases of hernia in which infection occurred, although the healing of the wound was delayed, none of the patients were detained in bed beyond the usual period of three to four weeks.

While investigating the results of "interval appendicectomies," we had necessarily to inquire into the histories of all the cases of appendicitis during the two years, and we think the following statistics, though not bearing on the main question, are sufficiently important to justify publication.

Operations for Appendicitis.									
7 7 22	1906.	1908.							
Total number of cases		216							
Operations in acute stage (gangrenous with abscess									
or with diffuse peritonitis)	111	128							
Deaths in acute cases	15	12							
Operations in quiescent stage ("interval appen-									
dicectomles")	€5	88							
Deaths in quiescent cases	Nil	Ntl.							
Percentage mortality (in all cases)	8.5	5.5							
Percentage mortality (in acute cases only)									
To sum up, out of every 100 primarily	aseptic	cases							

operated upon, 86.5 healed aseptically in 1906, and 92.8 in 1908. We hope that these statistics will prove useful and of interest to the practitioner and help him to give a patient a fair idea of the average chance of aseptic healing after the commoner operations. We have tried to make these records as accurate as possible and we have embodied in them the results of the work of four surgeons and three assistant surgeons.

In conclusion we must thank Dr. Slater, the head of the clinical laboratory of St. George's Hospital, for the kindly interest he has taken in our paper; and we are greatly indebted to him for the detailed description of the sterilising methods now in use.

THE RELATION OF ALCOHOL TO IMMUNITY.

BY P. R. PARKINSON, B.A., M.B., B.C. CANTAB. (From the Wellcome Physiological Research Laboratories.)

THE great amount of controversy which has arisen over the question of the action of alcohol on the human body has given rise to much experimental work on its action in animals. One of the chief interests of the question lies in the relation which alcoholism plays in the reaction of the body to infections. While much clinical evidence and general experience goes to show that large quantities of alcohol and the continuous use of moderate quantities in some individuals cause a lowering of the resistance to infectious disease, no definite evidence can be obtained as to its effect in small quantities. Experiments on animals have shown that there is in them a definite lowering of the resistance to infections when they are under the influence of alcohol.

The question as to how the alcohol acts does not seem to have been decided, though many statements have appeared to the effect that this drug lowers the resistance to disease by acting upon the phagocytes, and so inhibiting their activity. These statements have their foundation upon the fact discovered by Metchnikoff, that drugs such as opium depress the activity of the white cells so that there is less phagocytosis than in normal animals. Since, however, it is now evident from the work of Wright 2 that phagocytosis is dependent upon substances in the serum it seemed that it might be of interest to determine by means of the opsonic index upon which factor-serum or phagocytes-the alcohol does act in an alcoholised animal. Delcarde showed that animals when given alcohol succumbed during a course of immunisation against anthrax while the controls lived. Abbot showed that animals alcoholised are more sensitive to harmful effects of several micro-organisms—e.g., streptococcus, staphylococcus, and bacillus coli. Laitmen gave anthrax vaccine subcutaneously to six alcoholised animals and all died, while of four control animals only one died. Friedberger 6 has shown that one injection of alcohol increases the quantity of the antibodies while much alcohol diminishes them, but Fraenkel was not able to confirm this harmful influence.

Metchnikoff sums up the matter by saying: "Impairment of their [animals under alcohol] resistance was manifested by the inactivity of their white blood cells: alcohol therefore has a harmful action on phagocytes." Statements of a similar kind are quoted in the work by Horsley and Sturge. They say: "It is now proved that alcohol even in tiny doses paralyses more or less the white cells. Alcohol renders the white cells less alert, so that they remain passive and motionless in the presence of dangerous microbes." Woodhead has stated that alcohol has an action on the antibodies in the serum, which are regularly but distinctly reduced. Kruschilin observed in alcoholised

rabbits a quicker course of infection and a quicker sprouting of spores than in control animals; he considers that the activity of the phagocytes is inhibited by the alcohol; he used staphylococcus, anthrax, and the hay bacillus in his experiments.

The experiments detailed in this paper were made with the object of determining the effect of alcohol, firstly, upon the phagocytes; and secondly, upon the production of anti-bodies which were gauged by taking the opsonic index.

Method.—The opsonic index was estimated in the usual way. The animals (rabbits), which were treated with alcohol (diluted), were injected by the vein of the ear. In the animals subjected to continuous alcoholism the treatment was commenced with small doses and gradually increased, the injections being made every other day and the treatment continued from two to four weeks; a tolerance is gradually established and the doses can be increased; the maximum dose obtained was once 2.5 cubic centimetres of absolute alcohol well diluted in normal saline. The minimum dose commenced with was 0.1 cubic centimetre. Rabbitsshould not be repeatedly injected subcutaneously with even dilute alcohol, as necrosis is apt to occur at the site of injection.

Action of alcohol upon the phagocytes.—In studying this action the following method was used: the blood was dropped into 1.5 per cent. sodium citrate and centrifuged down; the supernatant citrate was then drawn off and the corpuscles were mixed with normal saline made up with the required strength of absolute alcohol and this mixture allowed to stand, with occasional mixing, for about one hour. The corpuscles were then centrifuged down and immediately used.

Small quantities of alcohol.—The first experiments were made with small quantities of alcohol in order to see if this had any effect, either stimulant or depressing, upon the action of the phagocytes. Dilutions of alcohol 1 in 100, 1 in 50, and 1 in 25 were made: human serum and staphylococcus aureus were employed, and in all the experiments human corpuscles were used.

```
50 cells. Index.
Normal corpuscles
                           + serum + cocci = 220 = 1
                    (1-25) + \dots + \dots = 218 = 1

(1-50) + \dots + \dots = 221 = 1
Alcoholised ,,
     ,,
                    (1-100) + ,,
                                     + ,, = 198 = 0.9
```

The conclusion from this experiment is that by treating white cells with the quantities of alcohol given no effect on phagocytic activity is apparent.

Stronger solutions of alcohol.—Dilution 1 in 5: The corpuscles were next treated with a very strong solution of alcohol, 1 in 5, with the following result :-

```
50 cells.
Normal corpuscles + serum + cocci = 212
Alcoholised , + , + , = 0
```

The white cells were here obviously much damaged by the alcohol and probably actually killed as the majority were broken in appearance and very granular.

Experiments were then made to determine at what concentration of alcohol the corpuscles are affected, and for this purpose two dilutions of alcohol were used for treating the corpuscles, 1 in 8 and 1 in 10.

```
50 cells. Index.
Normal corpuscles
                            + serum + cocci = 269 = 1
Alcoholised , (1-10) + ,, + ,, = 260 = 1
,, ,, (1-8) + ,, + ,, = 132 = 0.5
```

The phagocytosis in the last case is lowered to half the normal, and though the corpuscles were not broken up there was some evidence that the alcohol of this strength had acted upon their structure in that the outline of the nucleus in many cases was becoming irregular as though small "streamers" of nuclear protoplasm were projecting into the cytoplasm.

From these experiments it may be concluded that alcohol has no effect upon phagocytic activity until it is of such a concentration as to seriously injure the vitality of the cells. Moreover, it is practically impossible that it could occur in such quantities in the blood as to be in a solution of 1 in 8, at which dilution it begins to exert its effect upon the cells.

Effect of alcohol on the opsonic undex .- 1. Non-toxic dose of alcohol. A cubic centimetre of alcohol was injected subcutaneously and caused no apparent clinical effect. Blood was withdrawn 24 hours and three days after the injection and tested against staphylococci.

$4 hours —
   Corpuscles + normal rabbit serum + cocci = 211 = 1
            + alcohol ,, , + ,, = 285 = 1.3
Three days-
   Corpuscles + normal rabbit serum + cocci = 283 = 1
           + alcohol ,, ,, + ,, = 279 = 0.98
```

A small non-toxic dose of alcohol causes a rise in the opsonic index of short duration.

2. Toxic dose of alcohol. - The effect of this was studied by giving a rabbit a single large dose (4 cubic centimetres) subcutaneously. The clinical effect of this was respiratory distress and some collapse. The symptoms appeared in half an hour and lasted about four hours. The animal's serum was tested four hours and 24 hours after the injection.

```
Four hours-
    Corpuscles + normal rabbit serum + cocci = 380 = 1
              + alcoholic ,, ,, + ,, = 294 = 0.77
       ••
    Corpuscles + normal rabbit serum + cocci = 248 = 1
              + alcoholic ,, ,, + ,, = 269 = 1.08
A toxic dose of alcohol lowers the opsonic index for a few
```

hours, but recovery has taken place in 24 hours.

Effect of chronic alcoholism on the opsonic index. was treated with gradually increasing doses of alcohol, the injections being given intravenously every other day. Serum taken at various intervals of time gave the following results :--

```
Eleventh day-
                               Three weeks-
 Index to staphylococcus = 0.72
                                 Index to staphylococcus = 0.72
                                    ,, tubercle bacilli = 0.69
    ,, tubercle bacilli = 0.78
Sixteenth day-
                              Four weeks-
 Index to staphylococcus = 0.76
                                Index to staphylococcus = 0.78
    tubercle bacilli = 0.77
                                    ,, tubercle bacilli = 0.70
```

Chronic alcoholism produces a marked lowering of the opsonic index, although no toxic symptoms are produced.

Effect of alcoholism on reaction to vaccination.—A rabbit which was under the influence of chronic alcoholism was injected with a vaccine of 1,000,000,000 staphylococcus aureus and its reaction compared with that of a normal rabbit similarly treated.

Before the vaccine—				5	0 cells.		Index.
Alcohol rabbit	•••	•••	•••			=	0.79
Normal ,,		•••	•••	•••		=	1
24 hours after the vaccine—							
Normal rabbit				=	218	=	1
Vaccinated alcohol rabbit				=	206	=	0.94
" normal "	•••		•••	=	288	=	1.32
Third day after raccination—							
Normal rabbit				=	302	=	1
Vaccinated alcohol rabbit				=	229	=	0.7
" normal "				=	308	=	1
Sixth day—							
Normal rabbit		•••		=	203	=	1
Vaccinated alcohol rabbit				=	136	=	0.6
" normal "			•••	=	207	=	1

The effect of this vaccine on the rabbits shows that where a normal rabbit would respond to a vaccine with a considerable rise on the opsonic index a rabbit under the influence of alcohol shows reaction, the index not rising above normal. The injections were repeated, using a much thicker emulsion of killed organisms.

Before vaccination—	56	cells.		Index.

Vaccinated alcohol rabbit	=	357	==	1.06
" normal "	=	43 6	=	1.3
Ninth day—				
Normal rabbit	=	387	=	1
Vaccinated alcohol rabbit	=	352	=	0.8
. ,, normal ,,	=	476	=	1.26
Twelfth day—				
Normal rabbit	=	284	=	1
Vaccinated alcohol rabbit	=	197	=	0.7
,, normal ,,	=	296	=	1

The large dose was sufficient to produce a marked negative phase followed by a positive one; the negative phase brought the normal vaccinated rabbit's index down to the level of the alcoholised one after a slight rise in each case; from this point the reactions show a marked difference, the normal vaccinated rabbit's index mounts up to 1.3 while the alcoholised rabbit's index starting from the same level mounts up only to about normal. The reaction lasts rather longer in the case of the normal vaccinated rabbit.

These results show that one of the effects of chronic alcoholism on the animal's body is to act upon the mechanism which produces the anti-bodies in such a way as to render it less sensitive to the invasion of killed microorganisms so that the reactions are not so great as in a normal animal; it is interesting to note also that the negative phase is less marked in the alcoholised rabbit. It would naturally be inferred from such results that animals under the influence of alcohol would show less resistance to infections by living organisms than the normal animal, as has been shown by experiments referred to previously.

The next experiment therefore was to try the effect of such living cultures upon the reacting mechanism. A rabbit under the influence of alcohol was infected intravenously with a living culture of staphylococcus aureus and at the same time a normal animal was treated with an equal quantity of the same emulsion of staphylococcus; the variations in their opsonic indices were followed for several days; the rabbits showed no clinical signs except a slight loss in weight in each case. The opsonic index of the alcoholic rabbit before infection stood at 0.7. 50 cells were counted in each case.

Normal rabbit	+	,,	= 312 = 1
Infected alcoholic rabbit	+	,,	= 225 = 0.72
" normal "	+	**	= 364 = 1.16

These results show as would be expected from the previous ones that the production of antibodies as represented by the opsonins is very much feebler in an alcoholised rabbit than in a normal rabbit when both are infected with living microorganisms. In this case both animals survived the injection, and though they suffered from a prolonged negative phase both eventually showed a positive phase; the difference of reaction is marked, the alcoholised rabbit shows a much lower index during the negative phase and a less marked rise during the positive reaction, thus proving again that the alcohol has interfered with the reactive mechanism.

Though these results are definite for animals and probably show the method by which alcohol lowers resistance to disease in man the conditions under which the experiments are performed are not strictly the same in the two cases. The alcohol present in alcoholic liquors is not pure alcohol alone, but contains other substances which may in large quantities be equally deleterious; at the same time it is probable that such toxic substances would act in the same

way as the alcohol does, by depressing the activity of the reacting mechanism.

Another important difference to be remembered in applying these results to the case of man is that of tolerance. The experiments were carried out after a few doses of alcohol had been administered and such doses were given in gradually increasing quantities. In man, however, there may be the same dose, roughly speaking, continued over a great number of years, in which case it is probable that a high degree of tolerance being induced no abnormal condition of the reacting mechanism is incurred.

In those cases in man in which alcohol does lower the resistance to infections it is probable that it acts in the same manner as it appears from these experiments to act in rabbits, by its action on the production of antibodies and not from any action directly upon the phagocytic activity of the white cells.

Conclusions.—1. Alcohol in small quantities has no action upon the phagocytic activity. 2. It has no action on the phagocytic activity until it is present in 12.5 per cent. strength. 3. Small quantities of alcohol injected into rabbits may stimulate the production of antibodies temporarily. 4. A large dose of alcohol lowers the opsonic index for 24 hours. 5. Continuous moderate doses of alcohol cause a permanent lowering of the opsonic index. 6. The reacting mechanism to vaccines is much less effective in alcoholised rabbits than in normal rabbits; the difference is still more marked when living micro-organisms are used.

SOME COMPLICATIONS AND DANGERS OF NASAL SURGERY.1

By H. BELL TAWSE, M.B., Ch.B. ABERD., F.R.C.S. ENG.,

LATE HOUSE SURGEON AND CLINICAL ASSISTANT, HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE, LONDON, W.

During the last 20 years nasal surgery has made very rapid advancement, the technique has much improved, and areas which at one time were deemed inaccessible and dangerous can now be reached with comparative safety, while the vulnerable parts of the ethmoidal labyrinth, for instance, have been more clearly defined. In recent years the attention of the medical profession has been drawn to the importance of surgical procedure in many of the cases previously treated—and very often unsuccessfully treated—by douches, snuffs, &c. Medical men, as a rule, did not hanker after such cases, which seldom did credit to their treatment; and often the patients, in a miserable condition from headache, foul nasal discharge, cough, and expectoration, &c., dispensed with medical advice, and either resigned themselves to their condition or gave themselves up, body and soul, to the remedies of the unscrupulous quack. Nowadays there are few diseases of the nose that we cannot in some way ameliorate, and there are many sufferers that we can reasonably promise to restore to perfect health. Naturally the increased number and the magnitude of nasal operations have produced complications and dangers unheard of in pre-operative days, and it is on these more particularly that I propose to dwell, completing the imperfect record of personal experience by cases which I have observed under the care of others.

DISEASES OF THE MIDDLE TURBINATE.

The middle turbinate, by far the most interesting and important of the spongy bones, is very commonly the site of disease of varying forms and intensity, and from its close proximity to the openings of the anterior group of sinuses it will be obvious to you that alterations in its size must materially influence the drainage of those sinuses. Fortunately, in many of the cases of acute inflammation of those sinuses the inflammatory products force a way out and recovery speedily follows, but occasionally—and I venture to say more commonly than we think—the sinuses only partially empty themselves, and one is face to face with the beginning of a chronic sinus supparation.

Diseased conditions of the middle turbinate require its

partial or complete removal. It is said that fracture of the cribriform plate of the ethmoid has been caused by the use of the cold wire snare in this procedure. This I very much doubt, but I have seen post mortem a case where this structure showed a perforation supposed to have been caused by Walsham's scissors in removing the anterior end of the middle turbinate, death being due to suppurative meningitis.

A point which I should like to strongly emphasise is the importance of having free access to the middle turbinate before attempting its removal. I refer to the correction of deviations and obstructing spurs, which not only occlude the view but very frequently conceal an enlargement and prevent its complete removal. If this is not done the mucous covering of these deviations is almost certain to be damaged and troublesome adhesions between the septum and turbinates are extremely likely to follow and will be very difficult to cure. The surgery of the nasal septum was until a few years ago in a most unsatisfactory state. The operations were manifold and the armamentarium employed was a most extensive one, and the results in many cases were deplorable. Adhesions to the turbinates were common, perforations and sloughing of the septum were frequent, and I know of a case where collapse of the tip of the nose occurred and transformed a well-shaped into an ugly snubnose. A few years ago Killian introduced his now famous operation of submucous resection of the septum, and I can unhesitatingly recommend it to you for practically all cases of septal deviation. Carefully and skilfully done it has no equal. It will afford easy access to the diseased middle turbinates, it will render any after-treatment simple, and it will make it possible for you to obey the golden rule for successful nasal surgery-namely, to have efficient drainage.

By far the most important disease of the middle turbinal region requiring surgical intervention is polypoid degeneration, commonly called nasal polypi, and there is no pathological condition in the nose which demands such careful, thorough, and patient treatment. Associated as it often is with suppuration and sinus infection, it will be at once apparent to you that it is a prolific source of the complications which occur in nasal surgery.

Ethmoidal curetting, the only operation worth doing for nasal polypi and apparently a dangerous procedure, is one which in skilled hands is attended with brilliant results. The dangers I shall enumerate to you, but only the most important will be reviewed at length. They are: (1) hæmorrhagic effusion into the eyelids and orbits; (2) orbital abscess; (3) necrosis of the frontal bone; (4) necrosis of the superior maxilla; (5) fracture, puncture, and laceration of the cribriform plate, suppurative meningitis; (6) suppurative meningitis apart from injury; (7) severe hæmorrhage; and (8) optic neuritis and blindness.

The first of these, effusion into the eyelids and orbit, is very common and of no moment. Orbital abscess, very rare, requires external incision, as do necrosis of the frontal bone and superior maxilla, but such unfortunate occurrences should not deter one from thoroughly clearing out the disease. To be timid with ethmoidal curetting will certainly deprive the operation of much of its success.

I had the good fortune to see a case which well illustrates all the complications I have discussed and a few more. Double ethmoidal curetting was performed on a woman rather over 30 years of age, who was the subject of old-standing nasal polypi and ethmoidal suppuration. A few hours later both eyes were closed with hæmorrhagic effusion, and, as is usually the case, she had severe frontal headache. At night the temperature was 101° F., being 99.5° in the morning. This febrile condition persisted, although at the end of the first week the effusion had left the eyelids, and the headache was merely a dull aching heaviness. Four days later puffiness appeared over the right nasal bone and the nasal process of the superior maxilla, and in a few days fluctuation was made out. The abscess was freely incised; a little thin pus escaped, and some necrosed bone was soraped away; it was drained. A week after, during which time the temperature had varied from 99° to 102°, a similar but larger swelling appeared along the lower orbital margin and was similarly treated. A week later just the same happened in the right frontal sinus region and subsequently on other parts of the skull. By this time the headache had become intense, optic neuritis was diagnosed, the eyelids were cedematous, and drowsiness had developed. At night she was delirious, and occasionally in

¹ Founded on an address delivered before the Nottingham Medico-(Mirurgical Society.

the last two days of her life she had a rigor. The postmortem examination revealed extensive necrosis of the superior maxilla and frontal bone scattered in small patches, and giving the skull a worm-eaten appearance. The cribriform plate was reduced to a soft pulpy mass, and the crista galli of the ethmoid floated free in the pus of a basal meningitis. All the accessory sinuses contained pus. The case, I think, is unique, and fortunately so. Its gradual progression to a fatal issue occupied about five weeks and nothing seemed to influence its course.

The cribriform plate of the ethmoid—that bugbear of most nasal surgeons in their early days—is occasionally punctured, fractured, or lacerated, and fear of this has time and again led to failure. But really a little care in watching the position of the cutting end of the curette with regard to the plane of the cribriform plate will prevent any damage. It is not so easily punctured as one would imagine-access to it is through a narrow slit, I might call it, and to get there requires some force. Still, the indiscriminate use of a cup-shaped curette with the cutting edge pointing upward will undoubtedly injure this structure, and it was in much this way that another death I have seen occurred. The instrument was a Grünwald's curved curette, and although the cutting edge was mostly directed towards the orbit, at times it must have strayed towards the vertical plane, and then the damage was done. I need not recount to you the further history of the case beyond telling you that acute suppurative meningitis reached a fatal termination in four days. The symptoms in such a case are similar to leptomeningitis from other septic causes but more severe. The diagnosis is never in doubt and the treatment is always in vain. Operation need not be thought of.

Before finishing this fragmentary description of the dangers of ethmoidal curetting a word of caution will not be out of place in dealing with older patients—those over 50 years of age—the subjects of long-standing sinus suppuration and polypi. Many of them have on frequent occasions had polypi removed; the middle turbinate, or what remains of it, is in a state of degeneration, and the tissues are of a pale bluish anæmic colour. The nose is full of pus, and perhaps all the sinuses are infected, and the bone destruction is usually much greater than one can diagnose by the speculum and probe.

A very interesting case—one that well exemplifies the risks of old-standing nasal polypi and suppuration in old people—was that of a man, 70 years old, who for 40 years had been the victim of nasal polypi. Time and again the polypi were removed by the snare, only to recur in a few months. Every visit to the surgeon he vowed would be his last, and he actually went for two years with his nose completely blocked. However, this state of things could not continue; his health began to decline, the pus which he was swallowing ruined his digestion, whilst cough and expectora-tion repeatedly spoilt his night's rest. He was obviously breaking up; headaches—occasionally frontal and sometimes occipital, but oftener general—still further reduced his strength. His spirits flagged, and at odd times he fell into a drowsy, half-somnolent condition. The headache increased and became so excruciating that he was compelled to seek advice, hoping that another clearance of his nasal passages would relieve him, as it had done before. This time, however, it was thought that the nasal condition would not account for the intensity of the headache, but in the hope that the removal of pressure and the improved drainage would allay the pain the larger polypi were removed under cocaine and adrenalin anæsthesia with the cold wire snare. There was no improvement; the operation had failed to benefit the headache. 12 days later he died, and the course of the illness was particularly interesting. He gradually became drowsy, his temperature at times reached 102° F., and his repeated request was for something to relieve the headache. He retained his faculties to the end, even talked and made witty remarks. and only for a couple of hours before death did he become quite unconscious. Throughout his pulse was strong; he had but one rigor and had no convulsions. Optic neuritis was absent. Twitching of the right arm and leg appeared for a day, and brief cycles of Cheyne-Stokes breathing were noted. Unfortunately no post-mortem examination was made, and thus the diagnosis was in doubt. Was it a cerebral abscess or suppurative meningitis? I am inclined to think it was the former from the previous history, from the duration of the illness after operation, and from the absence of signs of

meningitis save in regard to the temperature and drowsiness. Moreover, I might venture further and suggest that the abscess was in the frontal lobe. The cerebral abscess, if he had one, was probably old-standing, and its latent energy was stimulated by fresh absorption from the raw surfaces left after the removal of the polypi. Therefore I should like to impress upon you the importance of early and thorough treatment of nasal polypi and ethmoidal suppuration and to remind you of the complication which may ensue in old-standing cases.

THE SURGERY OF THE FRONTAL SINUS.

The surgery of this sinus has progressed with leaps and bounds since Ogston in 1884 described three cases of empyema which he had treated by operation. There is still room for great improvement, and I look forward to the time when one will be able unhesitatingly to recommend the radical operation without being haunted by fears of osteomyelitis of the skull and meningitis and the lesser evils of a discharging fistula in the orbit and continuance of the nasal suppuration. I would not have you think that I condemn the operation. Far from it, but I think many cases have hitherto been unwisely subjected to operation when the only symptoms of the trouble have been a discharge of pus from the infundibulum and an occasional headache.

To begin with, the deformity left after the radical treatment cannot be lightly laid aside. The disfigurement is obvious, and subjects of the double operation acquire a weird physiognomy, especially as the capacity of the two sinuses frequently varies. In women this is always a serious matter. Obliteration of the sinus, the common operation, is sometimes impracticable from its size. One has then to face the alternative of keeping a drainage-tube in the infundibulum till all discharge ceases. And this is no trifling matter if you consider that a rubber drain protruding at the inner angle of the orbit has to be worn for a considerable time, and then a silver cannula has to be inserted to prevent contraction of the infundibulum, and may have to be used for many months or even years. The uncertainty and tediousness of this mode of treatment try the patience of the surgeon and more so that of the patient, and some have drifted into a hopelessly neurotic condition, whilst others have become confirmed hypochondriacs. A hospital patient once told me that if the discharge from the orbital fistula could not be stopped he would commit suicide, and he looked as if he meant it.

The more serious and almost universally fatal complications of the radical operation are osteomyelitis of the skull. meningitis, and cerebral abscess, and to illustrate the first of these I will take the case of a young girl who was a sufferer from intense right frontal headaches and chronic nasal discharge. The operation was performed by Killian's method but no bridge of bone was left to preserve the contour of the orbit. A drainage-tube was passed into the infundibulum, and it was kept there for a week, till the skin incision had healed, and was then removed. The cavity was packed daily with gauze through this opening. Evidently the cavity was not being properly drained, for at the end of the first week the temperature rose to 102° F. and for the next few days ranged from 99° to 101.5°. The wound was opened up and one of the ramifications of the sinus was found shut off and full of pus. The gauze packing had not reached this point; otherwise the operation area looked The wound was opened up and free drainage was established, the gauze packing being continued. A few days later the skin over the frontal sinus assumed that glossy appearance which, to my mind, is a bad omen in such cases. At first there was no pitting on pressure, but a deep-seated tenderness led one to suspect bone inflammation. The wound was again opened up and the tissues were raised to expose a little of the frontal bone. This was found roughened and the periosteum over it was thickened; a drop of pus escaped on incising it. Perfect drainage was established but failed to influence the course of the bony inflammation. Œdema of the forehead with tender spots here and there over the skull were a fitting accompaniment to marked drowsiness, intense headache, and other evidence of septic infection of the meninges. Slowly she sank, and during the last two days of her life she was quite unconscious. She died about five weeks from the date of operation. Post-mortem examination revealed patchy osteomyelitis of the skull and purulent meningitis. Scattered all

over were small areas of necrosis from which beads of pus oozed on pressure.

No operative treatment seems to arrest the progress of osteomyelitis of the skull—and even the very radical proceeding of incising the scalp from ear to ear and chiselling away the outer table of the frontal bone failed to stop the spread in another case. In this case the drainage was apparently inadequate, and if one reflects on the irregularity of the boundaries of the frontal sinus, on its overhanging anterior surface perforated by venous channels, one can easily imagine that when the skin and tissues are allowed to fall into position how liable a small pocket is to be cut off. Once this happens time alone is necessary for it to become septic, for it seems well-nigh impossible to make the parts aseptic during operation. The subsequent course of the case is well illustrated by the examples I have already given you.

After such a gloomy account of frontal sinus surgery you will wonder why the operation is done, but when you consider that the posterior wall of the sinus is very thin, that erosion imperils the meninges, and that blockage of the fronto-nasal duct from cedema, nasal polypi, &c., is not uncommon, you will, I think, allow that the operation is absolutely necessary in some cases, and when I relate to you the following interesting case you will agree that disease of the frontal sinus involves the patient in considerable risk.

The case was related to me by a friend of mine, who was called in consultation to see a man who lay in bed apparently prostrate with grief at the death of a relative. Physicians said his mental equilibrium had been upset, probably from shock, and that restoration to health was but a question of time. Surgeons could find no symptom warranting an operation; in fact, they decided that the case was a medical one. He had no pain, no headache, and no optic neuritis. The appetite was poor and the bowels were constipated. He was listless and apathetic, would speak when spoken to, but at other times he lay with his eyes closed and seemed asleep. Someone mentioned "nasal discharge" and the rhinologist was soon on the spot. He detected signs of old ethmoiditis, but careful examination failed to justify any surgical interference. The patient died suddenly a week later, and nothing but increasing drowsiness was noted to help towards a diagnosis. Post-mortem examination revealed erosion of the posterior walls of both frontal sinuses with exposure of thickened dura mater and ethmoidal disease. A large abscess was found in one of the frontal lobes, and this had ruptured into the ventricles and caused the patient's sudden death.

To sum up the treatment of frontal sinus suppuration. In cases where pus escapes freely from the frontal sinus and is producing no ill-effect on the general health, and only an occasional headache is complained of, and if the patient can be seen periodically, I think the risks of operation more than counterbalance the advantages. Intra-nasal treatment will suffice for the patient's comfort. If, however, any signs of cerebral involvement occur, if the health is undoubtedly suffering from septic absorption, if the headache is intense and persistent, or the infundibulum is narrower and is causing retention, then an operation must be performed.

A few not unimportant sequelæ which one notices after operation, and which, although not of vital importance, are responsible for much discomfort to the patient, might be Dryness of the throat and nose, sometimes with mentioned. crust formation, may follow turbinal and extensive ethmoidal operations, and after the latter I have seen occur what one might term a post-operative ozena. The risk of infection of healthy sinuses must not be lost sight of, and although this at times is unavoidable, still strict attention to the ordinary principles of antisepsis or asepsis will considerably reduce the risk. Acute inflammation of the middle ear and follicular tonsillitis as operative sequelæ need not be discussed, but before I finish there is one more interesting sequela that I wish to bring before you. It is the nervous breakdown which one occasionally encounters.

When considering the benefits that will accrue to the patient one must not forget that the removal of the diseased foci is not the only point at issue. One must satisfy oneself that the patient's confidence will stand the strain of perhaps a tedious and painful course of treatment, and one must be ready to banish all gloomy thoughts, to combat every evidence of flagging courage, and to make the patient feel

that both are successfully striving to produce an early and favourable termination to the trouble. Sometimes one fails; the patient breaks down and various aches and pains are complained of. They may be located in the head at one spot, or a general headache, or in the spine, or assert themselves as weakness in the limbs and joints. The female sex is not alone in the neurotic plight. A man of strong physique and of apparently well-balanced mind may give unmistakable signs of nervous collapse. Women suffer from painful adiregular menstruarion and discover some tender spot in the ovarian region and hurry to the gynæcologist, whilst others adopt the suggestion of friends and undergo protracted rest cures, courses of electrical treatment, &c. Do not conclude that the operation has caused this train of symptoms: it is the tedious after-treatment which has been too much for their nervous systems.

Nottingham.

SOME NOTES OF

A SEVERE CASE OF EXOPHTHALMIC GOITRE, IN WHICH TREATMENT BY X RAYS AND SOUR MILK APPEARED TO BE BENEFICIAL.

By J. C. NEWMAN, M.B., B.C. CANTAB., F.R.C.S. ENG.

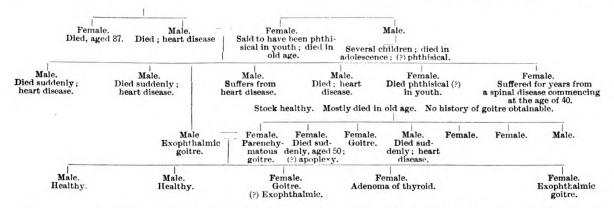

An unmarried woman, aged 31 years, consulted me in September last year for shortness of breath, general weakness, and nervousness. There was evident exophthalmos, the thyroid gland was markedly enlarged, the pulse-rate was 120 per minute, and fine tremors of the fingers were demonstrable. The patient was well nourished and did not appear to be any thinner than when I had last seen her about six months before. The following is the result of further examination. The action of the heart was visible, rapid, and forcible. The apex beat was in the fifth interspace just internal to the nipple line. There was a systolic bruit over the base, but no murmur of valvular incompetency was diagnosed. I considered that the heart was somewhat, but not excessively, dilated. The arteries of the neck pulsated forcibly, and there was a loud "bruit de diable" heard over the thyroid gland. Exophthalmos was very marked. Stellwag's and Grasse's signs were present. The thyroid gland was enlarged, the left lobe being more so than the right. The whole gland was very sensitive to pressure.

The history of the illness is as follows. About ten months previously I had attended the patient for a "bilious attack" with diarrhea and vomiting of unexplained origin. The attack passed off in two days. I noticed at the time a slight enlargement of the thyroid gland, but there were no exophthalmos and no unusual rapidity of the pulse, and the possibly true explanation of the attack did not occur to me. The mother has since told me that she was, then and after, anxious concerning her daughter's health, and that at about that time she noticed that she began to complain of the heat, although she had previously been a "chilly" person. She had no further symptoms, except occasional shortness of breath, for about six months, when she began to notice a feeling of weakness on exertion. This increased for three months, when she suddenly became very much worse, and was obliged to seek advice. In her past history there is nothing of importance, although before puberty she was considered delicate.

Her family history is interesting, and a scheme illustrative of it, so far as I have been able to trace it, is appended. Her father was more or less an invalid after the age of 39 years, when he had a "nervous breakdown." From this time he was liable to "totter as he walked" and at times he used to "shake a great deal." He developed "delusions" at 52. At 53 he had exoph halmic goitre, which terminated in acute mania and death at 55. The mother has had since girlhood a parenchymatous goitre. She has also suffered for many years from an "irritable colon"—i.e., the slightest indulgence in fruits, or even, at times, in green vegetables, will produce frequent large evacuations of undigested stools, accompanied by pain and much distress. She has been prostrated for weeks at a time from this cause. She is in other respects healthy. The family consists of two brothers,

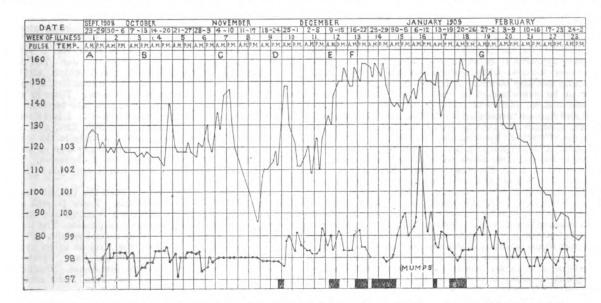

who are healthy, and three sisters. The eldest sister has an enlarged thyroid, and she and her family state that at one time she suffered from the symptoms of exophthalmic goitre, although she never sought medical advice for it. She is now in good health. The second sister has an adenoma of the thyroid gland. She enjoys good health, but says that the gland at times gets uncomfortably large. The third sister is the subject of these notes.

In consequence of her increasing illness Dr. Tooth was asked to see her, and his suggestion of Nativelle's digitalin accounts for the drop in the pulse-rate of the seventh and eighth weeks. Commencing with a quarter of a milligramme per diem on Nov. 8th and 9th, the same dose was given twice on the 10th and five succeeding days, when a single dose per diem was again given. The effect on the pulse is the more remarkable when it is considered that the patient was previously taking

was strictly limited, her society being practically confined to that of her mother, with an occasional short visit from a brother or sister. She was put upon a diet from which red meats, tea, coffee, and alcohol were excluded, and which consisted chiefly of milk and milk foods, fish, a little game, chicken, and bread and butter. The drugs employed will be discussed later. The course of her illness is indicated in the appended chart. Dr. J. S. Risien Russell, Dr. Howard H. Tooth, Dr. Hutchison, and Dr. H. Lewis Jones saw her in consultation with me. The pulse-curve on the chart indicates

The patient was kept in bed, the number of her visitors large doses of the tincture of digitalis. With the fall in the pulse-rate the patient certainly became more restful and composed, and she also slept better. Improvement, however, in other respects did not coincide. The thyroid did not decrease in size, nor was the palpitation much better. On Nov. 18th, while she was still taking a quarter of a milligramme of digitalin per diem, the pulse-rate suddenly, one evening, jumped to 118. An increase of the dose had no effect, and as she complained of feeling sick it was stopped altogether. However, on the 24th she vomited and hereafter the attacks of vomiting seem to account for the high

The upper line is the pulse curve and indicates the highest daily reading from the charts kept at the time. The lower line is the temperature curve. The letters on the chart indicate the general medicinal remedies employed, thus:—A. Tinct. belladonnæ and liq arsenicalis; B. tinct. belladonnæ and tinct. digitalis; C. digitalin nativelle; D. rodagen; E. opium and morphine; F. X rays; and G, sauerin. Attacks of vomiting are indicated by the blackened spaces

the highest daily reading from the charts kept at the time. Most, but not all, of the larger gross variations seem to be capable of explanation. Thus, there was for the first four weeks a gradual fall, presumably due to the rest in bed and other treatment. The rise at the end of the fourth week (Oct. 20th) was coincident with a very bad and persistent attack of palpitation, which was only partially controlled by the hypodermic injection of a quarter of a grain of morphia. From this time the patient steadily became worse. The palpitation became more troublesome, the thyroid grew larger, and the patient became more restless and distressed.

pulse-rate, nor is it surprising when one considers the terrible state to which she was reduced by them.

The condition of the heart was, on the whole, the bright spot throughout her illness. The dilatation which was present at the commencement was certainly increased during the period of vomiting and excessive rapidity of pulse, but never to the extent that one would have thought inevitable. There was a slight systolic bruit to be heard over the base, but I could never make out a murmur which I thought due to valvular incompetence, excepting after the last attack of vomiting on Jan. 24th. On that day and for about ten days

after there was a murmur which I took to be a mitral regurgitant blow. However, it had disappeared by the second week in February, and the heart now appears natural. As regards the action of the heart, it was for the first 13 weeks of her illness astonishingly regular, and at times a beat of over 150 per minute could be counted at the wrist. There were, however, times of faintness when it became imperceptible at the wrist, and during the later weeks it became very irregular in rhythm and force, at times very alarmingly so.

The most painful feature of the case was the vomiting. There were six definite attacks of this, lasting from two to seven days, and although the patient was occasionally sick between the attacks the sickness was on these occasions of a less malign character, relief being obtained by the emptying of the stomach. The first attack occurred on Nov. 24th and was at the time ascribed to the digitalin administered. It appeared to be controlled by cerium oxalate in usual doses. The second and subsequent attacks were more serious. Their duration is shown on the chart by the blackened spaces. Similar characteristics marked them all. A feeling of nausea would increase in intensity for about 24 hours and culminate in an act of vomiting, the vomited matter being usually bile. An hour or so later an attack of retching and vomiting would ensue, which would last from ten minutes to an hour and a half and completely prostrate the patient. After the cessation of the attack she would doze off into a broken and restless sleep for a few hours, from which she would be aroused by another attack of sickness. During the third attack the vomit, hitherto bilious, became coffeeground in character, and in the later attacks it was occasionally fæcal. There was always a tendency for the bowels to be loose during these attacks, especially towards the end of them, and after the last attack there was copious

The condition during these attacks was desperate, and indeed at the close of the fourth and sixth she appeared moribund. Although not absolutely unconscious, she was oblivious to her surroundings, and seemed much like a person in the last stages of a septic peritonitis, with the exception that she appeared to suffer more. With a parched tongue, her pulse uncountable, she lay in a state of muttering delirium, unable to raise her voice above a hoarse whisper or to control her sphincters. Having brought her to the lowest ebb, the vomiting appeared to cease automatically, and she began to make slow recovery. Of each of the remedies employed much the same tale may be told. Raising hopes at first, it seemed later to be overwhelmed by the severity of the disease. Cerium oxalate, tincture of iodine in large dilution, bismuth, soda and rhubarb, prussic acid, salol, carbolic acid, mercury, cotoin, adrenalin and cocaine, separately and in combination, atropine, hyoscine, hyoscyamine, chloretone, opium, and morphia is a melancholy list of the drugs employed. Of these the last two alone were of any real value, and they failed at last. Keeping the stomach empty of food had no effect. The organ filled with bile, the ejection of which was only a matter of time. Stomach lavage at times gave a temporary relief. Blisters or ice to the epigastrium were, I think, helpful for the nausea. Nutrient enemata were well retained throughout. During the earlier part of this period of vomiting the feeding was the matter of the greatest care, but in the later stages she was encouraged to take anything in reason that she fancied. She took tea, coffee, and brandy with apparent benefit. For the rest her food was composed of milk, a few eggs, and biscuits with large quantities of water. She was given strychnine hypodermically. Her body weight was fairly well maintained till the second attack of vomiting, which was accompanied by rapid and extreme wasting. Between each attack she would pick up, to be reduced to extreme emaciation by the succeeding one. The general medicinal remedies employed are shown by the letters on the chart. The belladonna was certainly useful throughout in checking palpitation and restlessness, but I could not see any general beneficial effect, although it was pushed to the verge of poisoning. The arsenic and tincture of digitalis were, I believe, useless, nor do I think the rodagen, though given in full doses, had the slightest effect.

On Dec. 18th Dr. Lewis Jones exposed the thyroid for seven minutes to the X rays. Subsequently I continued the treatment about twice weekly till Feb. 20th, 1909, exposing alternate sides of the gland at each application. The treatment certainly appeared to me to have some beneficial result.

and in this way. The second attack of vomiting had been accompanied by rapid wasting, in which the thyroid participated, but after the attack was over the gland became as large as ever within two days. This wasting occurred again during the third attack, after the commencement of the X ray treatment, but the re-enlargement was very much less marked, and after the fourth attack the gland remained in the condition in which it has been ever since—viz., the right lobe normal, the left lobe the site of an adenoma of about the size of a Tangerine orange. Her neck was at this time, and is now, smaller, according to her own account, than it has been for some years.

After the last attack of vomiting (Jan. 18th to 24th) the diarrhœa was considerably more troublesome than usual. The stools, to the number of six to nine daily, were large and watery, and were accompanied by much abdominal pain and tenesmus, and for part of this period there was melæna. Starch and opium enemata, bismuth, opium, cotoin, salol, and carbolic acid by the muth, opium, cotoin, salol, and carbolic acid by mouth produced no apparent benefit. After this condition had lasted for a week the patient was put upon milk soured by the lactic acid bacillus, in addition to a continuance of the treatment by opium and bismuth (which was continued for another five days). It is curious that from the commencement of the sour milk she began to have relief, not only from the diarrhoea, but from all her other symptoms, and that from this date her improvement was a steady one in every respect. The fact that the improvement followed so closely on the administration of sour milk, would, I suppose, suggest that the latter was not the prime cause of it. It must, however, be remembered that her diet at this time consisted of little else than milk, and that her stomach was dilated and probably in a condition of atony. Under these conditions her intestines may have received little else than soured milk, and this after they had been pretty thoroughly flushed out. The suggestion that her improvement was due to the exclusion of intestinal toxins, probably assisted by the fact that the activity of the thyroid had been reduced by the X rays, seems to me to be at the moment a legitimate one.

During the illness there were two intercurrent complaints of some interest. One was an exceedingly bad attack of conjunctivitis in both eyes (followed by a corneal ulcer in one), which commenced after her room had been filled with smoke from a smoky chimney. The other was a typical attack of mumps, which commenced on Jan. 7th, at a time when she was a little better, and which, although occasioning a good deal of pain and discomfort, appeared, on the whole, to do her very little harm. There is satisfactory evidence that no one who came into her room had been in contact with mumps except myself. I had attended such cases on Dec. 15th, 16th, 19th, 20th, 21st, and 22nd. An interval of at least two hours and a drive in the open of five miles intervened between my visit to any case of mumps and a visit to the patient at present under discussion. These facts seem to indicate that mumps can be conveyed by a noninfected third party.

Since the last date noted on the chart the patient has had some slight trouble from urticaria. There is still slight exophthalmos, the thyroid adenoma remains, and she has had on one or two occasions a little palpitation. The tremors have gone and she has regained her normal weight. She has been able to walk two miles on the level or to go upstairs without discomfort. The pulse-rate has kept between 80 and 90 per minute until the last few weeks. During the present month, however, there has been some return of tachycardia.

Bishop's Stortford.

THE ROYAL SANITARY INSTITUTE.—A meeting will be held on Dec. 8th, at 8 P.M., at 90, Buckingham Palace-road, when a discussion will take place on the Collection and Disposal of House Refuse, to be opened by Mr. J. S. Brodie, M.Inst.C.E., borough engineer, Blackpool. The chair will be taken by Mr. H. Percy Boulnois, M.Inst.C.E., and a general discussion is invited. The new museum providing greater accommodation, the committee is arranging for short exhibitions of sanitary apparatus. The first exhibition, showing working models of sewage distributers and sprinklers in action, is now open for inspection by members and others till the end of January, 1910. The museum is open daily from 9.30 A.M. to 5.30 P.M., and on Mondays to 8 P.M.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF HENOCH'S PURPURA; LAPAROTOMY; PNEUMONIA; DEATH.

BY J. BASIL COOK, M.D., B.CH. VICT., D.P.H. CAMB., SENIOR ASSISTANT MEDICAL OFFICER, EBNSINGTON INFIRMARY, W.

THE following case, having so many points of similarity with that reported by Mr. F. C. Pybus in THE LANCET of Oct. 9th, may prove interesting. The patient, a boy, aged 12 years, was admitted to Kensington Infirmary on March 11th, 1907, stated to be suffering from "acute rheumatism." Upon admission both knees and ankles were swollen, tender, and painful; there was a rash upon the legs which was considered to be peliosis rheumatica; the temperature was 98° F. and the pulse was 96. Three days later he had an attack of vomiting and complained of pain in the abdomen which was most severe in the umbilical region. On the next day the symptoms increased in severity, the vomiting was more frequent, and the vomited matter was blood-stained. There were diarrhoea and tenesmus, blood and mucus being passed in the stools. On the following day the patient was worse, having dulness in the left iliac fossa and a mass of something easily felt on the left side of the abdomen. The bowels were opened frequently, the motions still being blood-stained. A consultation was held, and the possibility of the condition having a purpuric origin was considered; but as the symptoms pointed so strongly to intussusception an operation was decided upon.

The abdomen was opened by Dr. H. P. Potter and a portion of intestine which felt like an intussusception was easily found. A careful examination showed it to be a portion of the small intestine which was considerably thickened for a distance of about 6 inches. Upon tracing this thickened piece of gut upwards and downwards one came upon normal intestine. The thickening was due to extensive extravasation of blood under the visceral peritoneum. Between the fingers this felt like worms in a bag. A few inches lower down there was a second piece of intestine of precisely similar appearance. No peritonitis was present and the incision was closed. The diarrhoea and vomiting persisted for several days but finally ceased on March 22nd, upon which day broncho-pneumonia developed on the left side. On March 23rd the cough was bad and the breathing distressed. A purpuric eruption appeared upon places where there was pressure. The urine was albuminous. From March 23rd to April 9th fresh crops of spots appeared almost daily upon various parts of the body, the head, trunk, limbs, hands (back and palm), and feet (dorsum and sole) being in turn affected. The patient began to get cedematous on April 11th, by which date the urine on heating was practically solid with albumin. The patient died suddenly on April 24th.

At the post-mortem examination there were found pleuritic adhesions and broncho pneumonia in the left lung, a patch of purpuric staining on the left ventricle, and large white kidneys. The other organs were healthy.

I am indebted to Dr. Potter, medical superintendent, for permission to publish these notes.

A CASE OF ASTHMA WITH VASO-MOTOR COM-PLICATIONS.

BY W. MILLER, M.D. EDIN.

IN view of the annotation on "Asthma and Urticaria" in THE LANCET of Oct. 23rd the following case may be of interest.

On Sept. 5th last I was called to see a lady, aged 34 years, who had been taken suddenly ill. It appeared that she had been suffering from a slight cold for some weeks. About midday on Sept. 5th she was stung by a wasp at the root of the second finger of the left hand. She applied a "blue bag." About 10 minutes later she had a paroxysm of sneezing, and as it passed off felt very ill and faint, and was with some

difficulty got to bed. When I saw her, about three-quarters of an hour later, she was propped up in bed, somewhat cyanosed, the respirations were 30 per minute and characteristically asthmatical, the pulse was 120 per minute, regular, but very soft and small, and the limbs and trunk were covered with large urticarial wheals. It was said that she was then better than she had been. Small quantities of brandy were given, and a spray, containing atropine and cocaine in a saturated solution of hyponitrous acid gas, was used frequently. Under this treatment the asthma subsided. The site of the wasp sting was freely scarified and a compress applied. An hour later I was hurriedly summoned, as "the uvula was displaced and choking her." The nettle-rash was now fading, the respira-"the uvula was displaced and choking tions were 20 per minute and slightly noisy, but not asthmatical, there was a constant dry cough, the pulse was 100 per minute, regular, but very weak, and there was considerable cyanosis. She had fainted once before my arrival. On examining the throat the uvula was seen to be very swollen, cedematous, and to a large extent blocking the isthmus faucium; the soft palate was also cedematous. I immediately swabbed the palate and uvula with a solution of adrenalin chloride, 1 in 1000, and as the patient fainted gave a hypodermic injection of digitalin. For an hour her condition remained most critical, she being almost pulseless. During this time the fauces were repeatedly swabbed with the adrenalin chloride solution, digitalin and strychnine were administered hypodermically, and, as she gradually improved, brandy was given by the mouth. Two hours later Mr. Cleveland Smith of Southend kindly saw her with me. condition was then quite satisfactory. The pulse was 90 per minute and of relatively fair volume, the respirations were 18 per minute and of normal character, the cedema of the palate and uvula had almost gone, and there were only faint traces of the nettle-rash. During the next fortnight there were slight asthmatical attacks which were controlled by the use of the spray; she then went to Brighton for 10 days, since when these have ceased. She is now (Nov. 1st) gaining strength, but the pulse is still feeble and there is palpitation on exertion.

There was no history of any previous asthma, but it was stated that her pulse had been commented on as being small by several medical men. There had been several previous wasp stings during the past summer, none of which had any constitutional sequelæ. On examining the site of the sting it was seen to be immediately over a small cutaneous vein, and it would seem possible that some poisonous matter may have been introduced directly into the circulation.

Rayleigh, Essex.

NOTE ON A CASE OF PITYRIASIS RUBRA PILARIS.

BY D. WELLS PATTERSON, M.B. DURH.,
ASSISTANT PHYSICIAN, DEPARTMENT FOR DISEASES OF THE SKIN, ROYAL
VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE; PHYSICIAN TO
THE HOSPITAL FOR DISEASES OF THE SKIN,
NEWCASTLE-ON-TYNE.

A YOUTH, aged 20 years, consulted me at the Hospital for Diseases of the Skin, Newcastle-on-Tyne, for an eruption which had first developed in March of this year. The disease first showed itself as an itching, red, scaly eruption of the face. After about a week it commenced to spread downwards on to the trunk and arms, and finally, in about a month from the commencement the legs were involved. At the same time the patient noticed horny points, developing on the chest first, but soon afterwards on the rest of the body, the arms, hands (especially the backs of the fingers), feet, and legs. Itching was at first very troublesome, but subsided soon after the onset. The patient states that there was no interference with his general health, and that he felt no inconvenience with the exception of the itching and a feeling of tightness in the skin generally.

The following was the condition on examination: The scalp showed a moderate amount of dry seborrhæa and the hair, though abundant, was dry and lustreless. The face was yellowish-red and covered with fine dry scales. The yellowish-red colour extended slightly on to the trunk and was also well marked on the front of the shoulders, in front of the elbow-joints, and on the anterior and posterior surfaces of the lower thirds of the forearms. It was also well marked on the lower part of the abdomen and over the buttocks. The skin

over the whole of the body, from the upper part of the trunk downwards, showed horny papules occupying the situation of the hair follicles, many of the papules being pierced by short broken hairs. In some places the papules were so closely set together that the skin felt like a very coarse nutmeg-grater. On the backs of the fingers the lesions remained discrete. There was very marked hyperkeratosis of the palms and soles, and in the latter situation the thickened epidermis was peeling off in large flakes. The nails were not affected. Apart from the condition of the skin the lad was perfectly healthy, and the urine was in every respect normal.

This case throws no light whatever on the obscure etiology of pityriasis rubra pilaris, and the whole condition was so marked that there was no difficulty in the diagnosis. Perhaps the one unusual feature of the case was the scanty amount of scaling on the body, though on the face this was well shown. My reason and excuse for publishing the case is that every case of this disease which is described may help to establish it as a clinical entity and to clear up disputed points in differential diagnosis.

ROYAL SOCIETY OF MEDICINE.

PATHOLOGICAL SECTION.

Autoplastic and Homoplastic Transplantation of Tumours of Mice — Dissemination of Caroinoma by the Blood Stream in Animals. — Experimental Production of Sarcoma in Mice. — Oophorectomy and the Uterus in the Rabbit. — Iransverse Lexica of the Spinal Cord. — Retro-peritoneal Teratoma Connected with the Spinal Canal.

A MEETING of this section was held on Nov. 16th, Dr. F. W. MOTT, the President, being in the chair.

Dr. M. HAMAND read a paper on Autoplastic and Homo-plastic Transplantation of Tumours of Mice. He said that he wished to bring before them some results of transplanting sporadic tumours of mice into the same mouse in which the tumour had arisen, as compared with corresponding transplantation into other spontaneously affected mice and in normal animals. The only previous attempts at systematic investigation of this kind, besides single cases reported by Loeb, were those recorded from the laboratory of the Imperial Cancer Research Fund. Four mice were inoculated with their own sporadic tumours with two successes; six mice with other sporadic tumours with only one success; three of the tumours employed were tested in normal mice, giving eight tumours in 325 inoculated mice. Loeb's cases were a mammary tumour of a rat re-inoculated into the same animal with positive results, and into two other rats with negative result, and also a tumour of a dog into the same dog and into three other dogs. The provisional results to which Dr. Haaland drew attention were: Of 17 spontaneously attacked mice after removal of the original tumour each inoculated with their own sporadic tumour, 16 had given continuously growing tumours; that gave a positive result in 94 per cent.; only in one the result was negative. Of 27 transplantations of the same tumours into other sporadic mice, only two had been attended with success (i.e., in 8 per cent.) Of the spontaneous tumours employed, 6 had been tested in normal animals; 3 of these were negative in 700 animals, while 3 others gave 32 tumours in 279 mice (i.e., ca. 12 per cent).

		Homologous transplantation.			
-	Auto-trans- plantation into sporadic mouse itself.	Other mice with sporadic tumours.	Young normals.	Old normals.	
2 cancroids	2/2	0/3	0/686	1 –

14 mammary adeno- carcinomata	13/14	2/20	28/251	0,12	
Total	16/17	2/27	32/979		

These experiments allowed some conclusions to be drawn both upon questions connected with transplantation in general and on certain aspects of the problems of cancer. First they illustrated very well the differences obtaining between autoplastic and homoplastic transplantation. Reintroduced into the organism to which they belonged-i.e., into the soil to which the cells were accustomed—they found all conditions for continued existence and growth. Quite different were the conditions in other individuals of the same species, of the same age and sex. By no other means could the existence of individual biological differences between animals of the same species be proved more clearly and the specificity of the milieu each animal represented be demonstrated more strikingly. The experiments showed the advantage which would be gained by the surgeon by employing tissues from the same individual in all transplantations, and showed that it was unreasonable to expect an equally good result with tissues from other individuals. Beside these general conclusions as to transplantation, the experiments had more direct bearing on certain problems of cancer. They demonstrated very strikingly a well-known fact—viz., the danger for the individual operated on if cancer cells were disseminated in the wound and the overwhelming probability that recurrence would follow upon such dissemination. On the other hand, they showed the relatively insignificant danger these cells represented to other individuals, even when introduced under most favourable conditions. last point had a direct bearing on one of the theories of cancer origin one now and then comes across-viz, that implantation of cancer cells from one individual to another played an important rôle in spreading the disease. Even if no other proofs existed to show that cancer always arose de novo in the organism attacked, the consideration of the facts elicited by these experiments showed the improbability of the transference of cancer cells from one individual to another having any etiological significance. Furthermore, these experiments threw light on hypotheses assuming cancer growth being due to a differential of avidity between tumour cells and body cells. The "avidity" of cells could only be tested in an imperfect and indirect way; the "avidity" of tumour cells by their behaviour on transplantation into normal animals, and the "avidity" of body cells by comparison of the suitability of the animal as soil for tumour growth with that of normal animals. In these experiments they had two cancroids which were tested by inoculation into 1000 young normal mice, of which 686 lived more than four weeks, but did not grow in a single animal. In this case it was difficult to assume any increased avidity on the part of the tumour cells. Each of those tumours was transplanted into its own mouse and here gave rise to progressively growing tumours. According to the theory they would expect that the body cells of the mice which allowed cells of such low "avidity" to grow, possessed a still lower degree of "avidity," and that, therefore, these mice would be more susceptible to transplantation of other tumours. But this was not the case. By exchanging grafts between the two animals in which these cancroids had arisen they did not obtain any growth, and these mice were not only refractory against tumours of low avidity, but when tested with another sporadic tumour which grew well in normal mice they also showed themselves completely refractory to this tumour of higher avidity. This experiment was only one instance of a series of similar experiments which all gave similar results. They showed that the conditions for tumour growth were far more specific than was allowed for by the supposition of a mere differential of avidities. In fact, the cells of each sporadic tumour were adapted for a specific milieu and only in this milieu were they able to unfold their real powers of assimilation and growth. The conditions for which two histologically indistinguishable tumours were adapted were so different that they could not be exchanged without the malignant mode of growth ceasing altogether. He had earlier attracted attention to a similar specificity of the conditions for growth, which under certain conditions might be exhibited by transplantable tumours. Two different transplantable tumours, a carcinoma and a sarcoma, each adapted to a different strain of mice, were mixed together and injected into mice of both strains. cells of each tumour showed in this case an elective power for that strain to which they were adapted, so that in each of the two groups of mice only those tumour cells grew which previously were adapted to this special strain. In these transplantations of sporadic tumours they met

with the same phenomenon, only even more pronounced; the conditions of growth were specific for each individual sporadic tumour. The phenomena of immunity to inoculation of cancer exhibited a parallel specificity as shown by Bashford, Murray, and Cramer, and by the author of the paper. While the conditions for progressive growth of the cells of a sporadic tumour were relatively seldom found in other spontaneously attacked animals, a preliminary growth lasting a few weeks was not so seldom observed. This phenomenon of preliminary growth was the same as that which was so frequently seen in transplanted tumours, and it suggested that simultaneous immunisation had to do with the final negative result. The experiments showed that tumour cells from another individual were far more susceptible to such a reaction than were the cells originally belonging to the same individual. The latter either did not set up any immunity reaction on their reintroduction in the body, or if such a reaction was set up, as seemed possible from Woglom's experiments made in the Imperial Cancer Research Laboratory on immunising mice with their own spleens, it had no effect against cells belonging to the same organism.

Dr. J. A. MURRAY demonstrated specimens showing the Dissemination of Carcinoma by the Blood Stream in Animals. Dr. B. R. G. RUSSELL spoke on the Development of Sarcoma arising during the Propagation of a Hæmorrhagic Adeno-carcinoma of the Mamma of the Mouse. After referring to the observations already made and published by Dr. Haaland upon this subject, the speaker proceeded to describe the histological and biological behaviour of a tumour of the mouse which also gave rise after 15 months of propagation to tumours composed of carcinomatous and sarcomatous elements. This tumour, strain "100," was the second tumour which had, in the laboratory of the Imperial Cancer Research Fund, given rise to secondary sarcoma development. The primary growth of the tumour in question was a hæmorrhagic adeno-carcinoma of the mamma of an old female mouse, and situated in the left groin. The tumour was removed by operation, but recurred, and finally the animal had to be killed, when it was found that there were present large metastatic deposist in the lungs. Material from the primary and recurrent growths was successfully transplanted and gave rise to the tumour-strain "100" of the Imperial Cancer Research Laboratories. No trace of sarcomatous tissue could be seen either in the primary, recurrent, or metastatic growths, and the tumours obtained by transplantation remained pure carcinoma for a period of 15 months. At this period it was noted that one tumour which hal grown for a very long period (57 days) in one mouse showed at one part a change in the character of the stroma whereby the normal connective tissue was replaced by an actively growing sarcomatous tissue composed of elongated spindle cells arranged in interlacing bundles. Three other very old tumours of this strain also showed the same change, whereas in none of the young tumours could any such change be seen. As it appeared that long residence of the carcinomatous cells in one animal played a rôle in the production of the sarcomatous change, a systematic investigation of the tumour was made with the object of proving or disproving this possibility. Pure carcinomatous tumours were transplanted, and a certain number of the resultant tumours were killed after 30 days growths, an equal number being allowed to grow until threatening ulceration from expansion of the overlying skin required the destruction of the animal. It was found that the tumours 30 days old always remained pure carcinomata. whereas the sister tumours which were allowed to grow for from 50 to 60 days or more almost invariably showed in some part of the tumour a neoplastic transformation of the stroma. Once initiated this sarcomatous proliferation rapidly spread throughout the tumour, and when these mixed tumours were transplanted the invariable result was the complete elimination of the epithelial constituent of the tumour. This occurred sometimes after one passage as mixed tumour, more usually after two or three passages. That the tumours thus produced were really sarcomata he regarded as being absolutely proved, and referred to Dr. Haaland's work upon the transplantation and metastasis formation of these sarcomata as having already fully proved this question. By choosing young tumours for transplantation it has been also possible to maintain parallel strains of pure carcinoma. which could always serve as fresh starting points for the study of sarooma development. In tumour "100" the pos-ibility of a primary mixed tumour could not be entertained; the

hypothesis that the sarcomatous cells were merely morphologically altered epithelial cells was also quite out of the question. He believed that in tumour "100" the epithelial cells induced after prolonged contact with the stroma cells, 50-60 days, a neoplastic transformation of the connective tissue cells, but did not attempt to premise more definitely the nature of that influence.

Dr. E. F. BASHFORD said that the three communications formed evidence of the very special nature of the investigation of cancer at the present time. The domination of cancer research by medical dogma had passed away and the investigation of cancer was rapidly advancing and could stand alone. Much that had been thought to be fundamental would be overthrown and much that was new would come out. It was now the turn for the investigation of cancer to modify pathological and medical doctrines in many directions. He did not deny the possibility of the parasitic etiology of cancer, but he did deny any analogy between cancer and the processes occurring in any known form of infective disease.

Mr. S. G. SHATTOCK showed the results upon the Growth of the Uteri of Double Oöphorectomy when carried out upon the young rabbit without the application of any ligatures and without injury and displacement of the rest of the generative apparatus. The result in question was a striking overgrowth of the uteri (which in the rabbit are two), as compared with those of an animal of the same size whether it had been pregnant or not. In the case of the human subject it was still doubted by some whether the ovary was the organ which dominated the growth of the rest of the generative apparatus. The evidence to the contrary in the case of man was in-direct and inconclusive. The case was parallel with that direct and inconclusive. The case was parallel with that of the ill-development of the testicles in cryptorchism. In scarcely any cases of bilateral cryptorchism was there evidence that the testicles were spermatogenic Nevertheless, such individuals might present all the external secondary marks of maleness. The right deduction must be that the hypoplastic undescended testicle functions for a short period only, and then rapidly becomes senile, and as in the case of the ovary the speaker held that a fully developed condition of the uterus was evidence that one or both ovaries had at some time functioned, though they might have afterwards functionally atrophied; the disparity presented between the size of the ovaries and that of the uterus might be erroneously read as a proof that the uterus had grown independently of any ovarian influence. In both sexes the speaker held that the external sexual characters were due to the production of an internal secretion, which probably acted upon the vascular supply of the accessory organs through the nervous system, but he thought that the production of this was in some indirect way dependent upon spermatogenesis or ovulation. There was a belief current amongst poultry breeders that section or partial excision of the oviduct in young hens led to atrophy of the ovary, the procedure being adopted to produce poulardes or fat birds for the table. This belief Dr. C. G. Seligmann and he had demonstrated to be quite erroneous by removing the oviduct in young birds examining the ovary when the birds were fully grown.

Dr. S. W SEWELL and Dr. H. HUME TURNBULL reported a case of Transverse Lesion of the Spinal Cord at the level of the sixth cervical vertebra. The patient was a boy, aged 14 years, who was knocked down by a motor cab, sustaining a fracture-dislocation at the level of the sixth cervical segment. Some movement in the right arm was retained and slight movement at the left shoulder, but there was otherwise complete paralysis of the limbs and trunk, with priapism and loss of sphincter control. Tactile sensation was diminished, but present below the level of the lesion. accompanied by marked thermo-anæsthesia. Death ensued eight weeks after the injury. The pathological examination dealt with (1) tract degenerations, ascending and descending, from the lesion; and (2) the changes produced in the cells of origin of the fibres injured. 1. Below the lesion descending degeneration, as shown by Marchi staining, was present to a marked degree in the crossed and direct pyramidal tracts, and to a lesser degree in the rubrospinal and vestibulospinal tracts. The comma tract was degenerated as far as the ninth dorsal segment and below this region Flechsig's oval area, and the triangle of Phillipe showed degenerated fibres, the latter tract as low as the third sacral segment. Marked degeneration was present on either side of the anterior fissure of the cord as low as the third

sacral segment, and since the direct pyramidal tract terminates in the upper lumbar region it was suggested that these fibres constituted the tract originally described by Mott from the corpora quadrigemina. The fact that these fibres descend to the upper sacral segments suggested some connexion with the voluntary control of the sphincters. Ascending degenerations were present in the direct cerebellar tract to the restiform body and in Gowers's tract, which divided into two parts in the upper portion of the pons, part passing to the cerebellum by means of the superior cerebellar peduncle, part entering the common fillet. At a lower level considerable numbers of fibres passed from Gowers's tract to the region of Deiters's nucleus. The posterior columns were totally degenerated as far as the gracile and cuneate nuclei, but even above the decussation of the fillet scattered degeneration was observed among its fibres. Ascending scattered degeneration was also present in the anterior ground bundles and in the continuation of these-i.e., the posterior longitudinal bundles—through the brain stem. Degenerated fibres from the posterior longitudinal bundle passed outwards to Deiters's nucleus, one through the valve of Vieussens, and some to the corpora quadrigemina. Degenerated fibres passing from the fillet into the lateral nucleus of the thalamus were also found. Scattered degeneration of coarse fibres was present in the pyramidal tracts above the lesion. Sections of the middle and lateral lobes of the cerebellum showed degenerated fibres from the direct cerebellar tract and Gowers's tract, sweeping both to the roof nuclei and dentate nuclei, and to the neighbourhood of the granular layer of the cortex. 2. Cell changes. The leg areas of the ascending frontal convolutions presented marked Betz cell changes from slight degrees of chromatolysis and nuclear excentricity to ghost cells, though a few cells were normal. Similar changes were present in the cells of the lower portion of the arm area, while the face and trunk areas presented no changes. No changes were seen in the large pyramidal cells or in the ascending parietal convolutions. Similar chromatolytic changes were present in the cells of Clarke's column, as also in many of the large cells of the red nuclei and Deiters's nucleus. No changes were seen in the large motor type of cells of the thalamus.

Mr. RAYMOND JOHNSON and Mr. T. W. P. LAWRENCE exhibited a specimen of Retro-peritoneal Teratoma connected with the Spinal Cord. The patient, a boy of 2 years and 9 months, had a swelling in the abdomen which had hear retried for three months. been noticed for three months. The lumbar spine presented a well-marked lateral curvature with its concavity to the left, and the left half of the abdomen was occupied by a large elastic tumour passing back into the loin. Although the nature of the case was evidently obscure, it was regarded as probably one of tuberculous disease affecting the left side of the bodies of the lumbar vertebræ and thus causing a lateral rather than the ordinary angular curvature. In accordance with this view the swellings in the abdomen and loin were regarded as chronic abscesses. An exploratory incision in the loin, exposing cysts containing sebaceous material, revealed the true nature of the case. It being evident that the removal of the tumour was impossible, a large cyst was opened and a drainage-tube inserted. The patient became progressively weaker and died about five months later. A partly cystic, partly solid tumour was found lying behind the left kidney, and intimately adherent to the spinal column. The tumour measured 10 centimetres in diameter and reached as high as the tenth rib. A portion of the tumour, 5 centimetres in vertical measurement, projected into the spinal canal, displacing laterally the extremity of the spinal cord and the cauda equina, but not compressing them. Microscopically, the tumour showed fibrous tissue, fat, myxomatous tissue, smooth muscle, cartilage, bone, skin, and tubular spaces lined with columnar or ciliated epithelium. In parts the structures present closely resembled feetal organs -bronchial tubes, intestine. The cysts contained sebaceous material, with hairs.

SECTION OF SURGERY.

General Spinal Analgesia.

A SPECIAL meeting of the Surgical Section, under the presidency of Mr. RICKMAN J. GODLEE, to which members of the Section of Anæsthetics were invited, was held on the afternoon of Friday, Nov. 19th, to listen to an address upon General Spinal Analgesia by Professor T. Jonnesco of the

University of Bucharest. The chief points of the method introduced by the lecturer are indicated by our description of the demonstration given at the Seamen's Hospital. The address was followed by a number of lantern slides illustrating various operations in progress under spinal analgesia. Trephining, ovariotomy, and removal of the lower jaw were amongst the operations depicted, and a striking slide was one showing a surgeon operating upon his own groin. Professor Jonnesco was warmly thanked for his address and a number of questions were put to him, to which he replied in French, the language in which his address was delivered.

CLINICAL SECTION.

Pneumococoal Colitis.—Primary Hyperplastic Tuberoulosis.— Exhibition of Cases.

A MEETING of this section was held on Nov. 12th, Mr. A. PEARCE GOULD being in the chair.

Dr. W. HALE WHITE, Mr. J. P. LOCKHART MUMMERY, and Dr. H. BRUCE-PORTER contributed a paper on a case of Pneumococcal Colitis with hyperpyrexia and severe hæmorrhage treated by appendicostomy. The authors stated that they had recorded the case because, in the first place, it was, they believed, unusual for a diagnosis of colitis due to pneumococcus to be made during life and confirmed by bacteriological examination; secondly, because it illustrated the difficulties of such a case and the successful treatment of hyperpyrexia by cold sponging—they especially drew attention to the beneficial effect of having run iced water through the colon; and thirdly, the case illustrated the value of appendicostomy as a means of stopping severe bleeding from the colon. Before the patient came under their notice the bowel had been washed out from the anus by intestinal douches without in any way controlling hemorrhage, nor did the same method of applying hazeline and water have any effect during the four days it was tried before doing the appendicostomy. While the patient was in a nursing home she took her food very well, and on several occasions half an ounce of sterilised olive oil was injected under the skin; this was always completely absorbed, and thus the case showed the occasional advantages of that little-used method of feeding.

Mr. W. GIFFORD NASH described a case of Primary Hyperplastic Tuberculosis of the Stomach and Duodenum. He said that tuberculous disease of the stomach was very rare, and of the duodenum almost unknown. Most of the cases reported had been instances of tuberculous ulceration of the stomach, secondary to tuberculous disease elsewhere. of hyperplastic tuberculosis of the stomach had been recorded by Mayo Robson and Beadles. Probably that affection had been mistaken for malignant disease. The case related was that of a woman, aged 33 years, who had suffered from gastric derangement for two and a half years and signs of pyloric obstruction for six months. The stomach was extremely dilated and a tumour was felt at the site of the pylorus. There were no signs of tubercle elsewhere. Operation revealed an elongated hard mass occupying the pyloric end of the stomach and the first part of the duodenum. stomach and omentum were covered with tubercles. Gastrojejunostomy was performed, with great relief of symptoms and improvement of the patient's condition. At intervals of 11 weeks and 14½ weeks after operation the abdomen was opened and drained of ascitic fluid. The patient died five months after the original operation, and no post-mortem examination was obtainable. - Dr. F. PARKES WEBER related a case of carcinoma of the bile-duct in which at the necropsy tuberculous tumours were found to be present.—Dr. H. D. ROLLESTON said that he had seen tumours which had been thought to be tuberculous turn out to be minute malignant growths -Dr. W. CAMAC WILKINSON (Sydney) described how the diagnosis between cancer and tuberculosis could be settled by the use of tuberculin.— Mr. NASH explained that he had come to the conclusion on clinical grounds that the miliary tubercles were tuberculous.

Mr. Pearce Gould described a case in which he had removed from the patient a Vesical Calculus weighing 8 ounces when fresh; the stone had formed with great rapidity in the bladder.

Dr. ROLLESTON and Mr. G. D. H. CARPENTER showed a case of Scleroderma with Sclerodactyly. The patient was a woman, aged 30 years, who was shown at the Clinical Society in 1901 as generalised scleroderma with Raynaud's disease. Symptoms of pain and numbness in the hands and,

to a less extent, in the feet began in 1895. The sclero-derma over the face, arms, and hands had advanced, whilst the feet and legs had recovered. The hands showed considerable ulnar deflexion and were flexed, claw-like, and almost immoveable. Attacks of local syncope and local asphyxia still occurred in the hands. During the last ten years she had had thyroid, iodides, and various vaso-dilators without any relief. She had always received benefit from electrical treatment. As the result of that and of massage and passive movements of the fingers there had been considerable improvement.

Dr. T. D. SAVILL showed a patient, a married woman aged 56 years, as the sequel of a case of Scleroderma of the Extremities (sclerodactylia, acroteric scleroderma of Hutchinson) associated with a previous and family history of angio-neurotic cedema. The patient had had attacks of anglo-neurotic ædema throughout life. The patient's mother and one of her two daughters also suffered from attacks of angio-neurotic ædema throughout life. The patient's attacks of angio-neurotic cedema ceased two and a half years ago, when the hands and feet first began to get hard and stiff. When she was first shown to the section in April last she could walk easily, but now only with the greatest difficulty. The thickening of the skin had extended up the limbs. The joints had become stiffer and more creaky, showing that changes were taking place within the joint structures as well as in the skin around. In spite of careful diet and medicinal and electrical treatment she had become progressively worse. A discussion followed, in which Dr. J. GALLOWAY, Dr. W. P. HERRINGHAM, Dr. ROLLESTON, and Dr. SAVILL took part.

Mr. ARTHUR H. EVANS showed a patient on whom he had performed the operation of excision of the larynx, of part of the pharynx, and upper end of the esophagus for malignant disease (squamous-celled carcinoma) of those structures.

Mr. T. H. OPENSHAW showed three cases. The first was one of Rheumatic Spondylitis with Torticollis. The second was a case of Rheumatic Spondylitis with Torticollis and Atlo-axoid Subluxation. The third was a case of Myopathy, infantile type. In the list of cases it was described as Batten's Frog-child. The patient, a boy aged 7½ years, first came under Mr. Openshaw's care in April last. He had never been able to walk. He could move his arms and legs till the onset of measles at the age of 18 months. After that he could not move his legs. His mental condition was excellent. He could not stand, even with aid. He made no effort to hold himself up. His general muscular condition had improved. He could now sit up unaided by pressure of hands on the floor. He could not stand on his feet, but the leg movements were stronger than on admission to hospital.

SECTION OF ANÆSTHETICS.

Heart Massage in Chloroform Syncope.

A MEETING of this section was held on Nov. 5th, Mr. R. GILL, the President, being in the chair.

Dr. VIVIAN B. ORR read a paper on Heart Massage in Ohloroform Syncope, with a report of a successful case. Dr. Orr said that the history of the evolution of this treatment with the information obtained from experiments on both cold- and warm-blooded animals showed that there was reasonable ground for testing its applicability to man. The inadequacy of the usual methods of restoring life in cases of heart failure under anæsthetics seemed undeniable, while, in the light of both written and verbal evidence, the claims of massage appeared to be clearly established. The different indications, the various possible modes of action, and the technique were discussed. The sub-diaphragmatic route was shown by results to be the preferable method of reaching the heart; 10 successful cases had been reported resulting from this procedure. The most difficult point to decide was the exact moment when this treatment should be applied. The higher nervous centres seemed to be irreparably damaged before the lower centres, and these again before the intrinsic heart vitality, and cases were cited which exhibited a return of both circulation and respiration for some hours, with no return of consciousness and ultimate death. If massage were performed within five minutes of the heart arrest there was a reasonable prospect of a favourable result if efficient lung aeration were maintained. Valuable time was often lost in necessarily

futile injections of stimulants, while the methods of aspiration, simple or electric puncture, electricity, and combined pressure on the lower limbs and injections of Ringer's fluid with adrenalin had not so far proved successful measures in man. The patient in the case recorded was about to be operated upon for gastric trouble when the heart failed. Mr. Charles Stonham opened the abdomen and massaged the heart from below the diaphragm from three to four minutes after the failure. In response to stimulation, the heart beats returned and the patient completely recovered.

Dr. DUDLEY W. BUXTON congratulated Dr. Orr upon his paper and the able résumé he had given of the subject. Dr. Buxton alluded to the various physiological factors which produced heart failure under chloroform and the circumstances which, arising during anæsthesia for a surgical operation, would tend to increase the danger of its occurrence. He pointed out that circulatory failure, although often associated with respiratory difficulties which themselves were adjuvant towards causing heart standstill, was directly the result of chloroform dosage, and its degree varied directly as the strength of the vapour inhaled. He discriminated between the various conditions at work when cardiac failure arose, emphasising the importance of their recognition in order that appropriate treatment should be pursued. The abdominal route without incision into the diaphragm was, he believed, the best one for heart massage, and he contended that that measure should not be unduly delayed if the case were at all appropriate, as the surgical procedure involved did not increase the patient's risk seriously. He pointed out that other subsidiary measures were necessary, but deprecated the use of electrical stimulation of the heart.

Dr. E. H. STARLING mentioned a case of a weakly child, aged 11 months, who required the needling of a cataract. Chloroform was given from a Junker's inhaler and was taken well. When the child was under, the head was slightly raised to adjust the towels, when both the pulse and the breathing ceased. The head was lowered and artificial respiration performed, while ether and strychnine were administered hypodermically and a warm saline solution was injected into the rectum. Fingers were passed up under the ribs and the heart compressed five or six times, when a gasping inspiration was taken, and the heart was heard to beat again, after which gradual recovery took place. He thought it essential that artificial respiration should be continued for some time after the heart recommenced to beat.

MEDICAL SOCIETY OF LONDON.

Treatment of Irigeminal Neuralgia.

A MEETING of this society was held on Nov. 22nd, Dr. SAMUEL WEST being in the chair.

Mr. JONATHAN HUTCHINSON read a paper on the Operative Treatment of Epileptiform Trigeminal Neuralgia. He sum-marised his experience of 31 operations on the Gasserian ganglion for epileptiform neuralgia of the fifth nerve, with especial reference to objections that had been raised against surgical intervention in this disease. First, with regard to the risk or mortality of the operation, he held that it was unfair to quote the early statistics, which undoubtedly gave a high percentage, as being true at the present time. about 20 per cent. of deaths (1896) the mortality had come down, in practical hands, to about 5 per cent. cases adduced not one had ended fatally; all had recovered. As to deformity resulting from the operation, he pointed out that this entirely depended on the method adopted. If a small flap was turned down from the scalp only, if only the necessary amount of bone was removed and the zygoma was not divided, practically no deformity ensued. It was, in fact. sometimes difficult to tell later by appearance on which side the operation had been done. As to the anæsthesia of skin and mucous membrane, this was generally of little con-sequence. The cranial anæsthesia was, however, more serious as the patient was left liable to ulceration from the unnoticed access of any septic dust. If the modification of the operation which Mr. Hutchinson had described was practised—namely, leaving the ophthalmic trunk intact—all danger to the eye was avoided. Out of the 30 cases this modification was carried out successfully in 26. In the other 4, in which the eye and forehead had

been left anæsthetic, some ocular complication had happened in all, but in only one had it proved serious. As regards the objection raised to the operation that it was not a radical or permanent cure, the evidence was steadily accumulating that in nearly all cases no return was to be feared. Mr. Hutchinson's first case dated 12 years ago, and even longer periods of cure had been observed. The operation did not prevent headache or neuralgia occurring on the opposite side of the head, and sometimes curious pains associated with circulatory trouble persisted or came on later. It was a matter of importance to avoid operation in patients obviously neurotic. Neurotic symptoms were as a rule absent in true epileptiform cases. In none of the 30 cases had there been any complication as regards sepsis or severe shock. In fact, recovery was rapid and uneventful. The average age of the patients was 52 years. The great difficulty of the operation arose from hæmorrhage, and in one case the recurrent bleeding from the distal end of the middle meningeal artery had necessitated a second operation, and the pressure of the blood-clot had led to some oculomotor paralysis on that side.

Dr. WILFRED J. HARRIS read a paper on the Treatment of Trigeminal Neuralgia. He said that he would restrict his remarks on treatment, for the most part, to that form of neuralgia of the fifth cranial nerve which was characterised by the definiteness of the pain area, corresponding roughly to the anatomical distribution of one or more branches of the nerve. Further, all neuralgias were definitely excluded in which there was any detectable cause of irritation of the nerve, either central or peripheral. The pain, moreover, almost invariably came on in severe spasms, varying in duration from half a minute to half an hour, and there might be intermissions of many months, or even of years, in which the patient was completely free from pain. With that exception the pain continued year after year, until operation of some kind, or death, brought relief. No cause had yet been fully proved for that terrible disease, though various slight changes in the Gasserian ganglion and in the peripheral nerves had been at times described. The sexes appeared to be about equally affected. Thus, of 265 cases, 144 were men and 121 women. There seemed, however, to be a very definite predilection for the disease to attack the right side, for of those 265 cases 179 were on the right side and 80 on the left side, while 6 cases were bilateral. Thus the right side appeared to suffer more than twice as often as the left side. The character of the pain was sometimes exactly simulated by other forms of trifacial neuralgia, particularly dental neuralgia. True trigeminal neuralgia affecting the first or ophthalmic division of the nerve alone was much less common than of the second or third divisions, and, indeed, he had only met with one such case. Yet supra orbital neura'gia was common enough as a reflex from errors of refraction and other similar causes, and it was especially severe as a post-influenzal neuritis. The diagnosis of the site of the cause of the pain was most important in estimating the probable results of any projected treatment, and it practically came to this: that if the pain was referred along one or more branches of the nerve, and there was no trace of any anæsthesia or analgesia or other signs of trophic impairment, such as muscular wasting or glossy skin, then the site of the cause of the pain was surely peripheral, and careful search must be made for any source of peripheral irritation, such as a carious tooth, an unerupted and impacted wisdom tooth, &c. During the last 12 months he had seen 29 cases of true trigeminal neuralgia or tic douloureux, 24 of which he had treated by injections of 80 per cent. alcohol. Of the remaining five cases, three refused treatment by injection; one, a case of bilateral neuralgia involving both second divisions of the fifth during the last 42 years was sufficiently relieved by butyl chloral hydrate and gelsemium as to render injection treatment unnecessary. The remaining case, a woman, aged 58 years, who had suffered only three months with neuralgia of the right third division, died suddenly from angina and cardiac infarction while butyl chloral was being tried. Of the 24 cases which he had treated by alcohol injection, 20 appeared to be so far completely successful as regards entire disappearance of the pain. Two of the remaining four cases were partial failures. If the needle were pushed in as far as 24 inches when searching for the foramen ovale it was likely to pierce the wall of the pharynx, and if

any alcohol was then injected the patient would recognise it by the smell and by its burning sensation on the back of the tongue. This was of no consequence. It must be distinguished from the sensation of trickling along the lower jaw and tongue that the patient would notice when the foramen ovale was being successfully injected owing to the action of the alcohol upon the lingual and inferior dental portions of the nerve. Well-marked pruritus might be sometimes complained of in the area of nerve-distribution after a successful injection into the nerve trunk. Of his 29 cases of true trigeminal neuralgia, 9 were men and 20 women. 13 cases affected the third division only and 8 cases the second division only, while only 2 appeared to affect all three divisions of the nerve, and in two cases the first and second division and the second and third divisions were affected together, both requiring treatment. 18 of his cases were on the right side, 9 on the left, while in 2 cases the pain was bilateral.

Sir Victor Horsley said that he had removed the Gasserian ganglion in 149 cases in patients of varying ages. He found that the death-rate was 7 per cent., but that really only applied in patients over 50 years, for he had never lost a patient under the age of 50 years. In regard to the deaths, one was from accidental sepsis at University College Hospital, and the others were all cases due to the arteriosclerosis from which these patients suffered. The operation was of course difficult, but this was not insurmountable. He considered that the so-called mortality and the so-called disadvantages of the operation were undoubtedly greatly exaggerated. He had employed the method of injecting alcohol with the view of avoiding the Gasserian operation. The cases in which the best results were obtained from alcohol injections were those which were strictly localised to one division of the nerve. Each case, however, must be dealt with on its own merits, but the general procedure was to recommend injection of alcohol first and afterwards, if necessary, resort to the removal of the Gasserian ganglion. He thought that the disadvantages of the removal of the ganglion were really more a matter of imagination than of clinical fact.

Mr. C. A. BALLANCE said that the dangers of the operation had been gradually getting less and less. He considered that it was the right thing where possible to inject alcohol before resorting to severer measures.

Dr. L. G. GUTHRIE pointed out that the severe condition of trigeminal neuralgia did not threaten life. He did not think it was desirable that operation should be performed on any young subject for trigeminal neuralgia.

Dr. T. Grainger Stewart said that those cases which would benefit by medicinal means would not accept operation. In those cases in which he had tried alcohol injection he had been very successful.

After Mr. HUTCHINSON and Dr. HARRIS had replied the meeting concluded.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Empyema Thoracis.

A MEETING of this society was held on Nov. 11th, Dr. E. H Davis being in the chair. The evening was devoted to a discussion on Empyema Thoracis.

Dr. JAMES DRUMMOND opened the discussion with a reference to the disease as seen by the general practitioner. He said that empyema could hardly be regarded as a separate specific disease, but rather as an accident or sequela, arising in the course of, or in consequence of, some other preexisting morbid process. It was with this period, before empyema had declared itself, and while the case was under the observation of the general practitioner, that he had been asked to deal. Once empyema was established, the case was no longer a medical one, and he had no hesitation in saying that the sooner it was dealt with by the surgeon the better. He mentioned only a few of the principal diseases in the course of which empyema might occur. In his experience pneumonia had been the precursor in nearly all the cases of empyema the onset of which he had observed. It might occur in the course of specific fevers, such as enteric fever, scarlet fever, measles, and influenza, but he was not sure that in all such cases a mild

type of pneumonia might not have been present. In fact, in many of the cases referred to pneumonia was undoubtedly present as a complication, and the eventual development of empyema in some of them led him to think that probably some degree of pneumonia was present in all. Next in order of importance in the causation of empyema he placed septic conditions of the lungs and abdominal viseera. Septic infarct, gangrene, and bronchiectasis would naturally lead the medical attendant to look out for empyema as a sequela. In his own experience, before the days of immediate operation for appendicitis, he had seen empyema develop in at least two cases which had gone on to suppuration of the appendix. Tubercle in itself was not often followed by empyema, and, as Dr. T. Beattie had pointed out, when it did occur it was usually a result of some added infection. In quite a number of cases there was no history of a previous illness. The medical man was consulted because a child was not "thriving"; there might be no rise of temperature, no cough, and no dyspnœa or other prominent symptom beyond emaciation, but on examination of the chest dulness over one or both bases might be found, leading to the suspicion that fluid was present, and on aspiration pus might be detected. illustrate the difficulty and uncertainty in the diagnosis of empyema he related a case as follows. He was called to attend a woman who complained of pain and swelling in her right side, accompanied by dyspnœa and cough. examination he found all the symptoms of fluid in the chest at the base of the right lung. He introduced a needle in the fifth or sixth interspace in the axillary line and drew off a syringeful of pus. She was operated on for empyema next day, and a large quantity of pus was withdrawn. Part of a rib was resected and the cavity washed out and drained. After a few days it was discovered that numerous pieces of membrane, clearly the daughter cysts of a hydatid, were present on the dressing, showing that the case was one of suppurating hydatid and not true empyema. The pus had found its way behind the liver and diaphragm and burst into the pleural sac. The case did well after a counter-opening had been made through the abdominal wall and the cavity irrigated with weak iodine solution. He purposely avoided making more than the briefest reference to bacteriology in connexion with the causation of empyema, but in his opinion empyema was a question of bacteriology from beginning to end. Temperature observations, auscultation, and percussion were useful adjuncts to a correct diagnosis, but all of them were fallible. The nearest approach to infallibility was, in his experience, to be found in the prompt and frequent use of the aspirating syringe and microscope. As an early diagnosis in such cases was all-important, he urged the prompt and repeated use of the aspirating needle before the lung had become irretrievably collapsed by pressure, and both surfaces of the pleura had become permanently thickened. With ordinary care as regards sterilising the skin and instruments, he had never seen the slightest bad effect from the use of the needle. If there was not time to sterilise the skin of the patient by means of scrubbing and antiseptic dressings, the site of the puncture should be previously painted over with liniment of iodine. When pus was found in the chest the case should be handed over to the surgeon at once. For the development of empyema there must be some antecedent local or general disease, usually dependent on, or at least associated with, the presence of a microbe, and in the great majority of cases, if not in all, the offender was the pneumococcus. In the course of an attack of pneumonia presumably a certain amount of pleurisy took place, with some degree of effusion of serum or lymph. This fluid instead of being re-absorbed became infected with a specific organism, and the resulting collection of fluid was an empyema. The large majority of cases of pleurisy were due to the presence of tubercle; this condition, however, seldom ended in empyema, so that some other organism must be usually, if not always, the deciding factor in producing empyema.

Professor H. J. HUTCHENS dealt briefly with the bacteria found in the pus of empyemata, and pointed out that in many cases the organisms were well-known inhabitants of the alimentary canal. Dr. S. J. Gee had long ago drawn attention to the fact that in empyemata of children the mesenteric glands were caseous. Professor Hutchens mentioned that in the pus from an empyema recently examined in his laboratory an organism was found which appeared to be

identical with the organism described by Dr. D. W. Carmalt-Jones, which he had found in some cases of bronchial asthma.

Dr. David Drummond said that the primary cause of empyema was pneumonia. It was 22 years ago that he first thought the association of pneumonia and empyema was more than accidental. If the temperature rose after the crisis of pneumonia aspiration should be performed on the tenth day, and without an anæsthetic if the patient would allow this. The needle should be inserted where the dulness was greatest and the vocal fremitus (which never entirely disappeared) was least. For testing the vocal fremitus he always used the single stethoscope. All the signs of simple and purulent effusions were the same. If there was diminished dulness at the end of one week the case was not one of empyema. Tuberculous disease did not follow pneumonia.

Mr. A. E. Morison made a communication on the Surgery of Empyema in Adults. He said that empyema was a more serious condition in adults than in children because it was more frequently complicated by tuberculous infection, by alcoholism, by organic diseases, especially those affecting the kidney, and by glycosuria. The treatment of both ought, in his opinion, to be surgical. It was a simple matter to evacuate the pus by the aspirator and recovery had followed a simple aspiration, but this result was so infrequent that no practical importance could be given to it. The greatest use of the aspirator (including the exploring syringe) was to discover the presence and the position of pus. As a rule the question whether the empyema was general or localised could be determined by ordinary physical signs, but this was not always possible. In localised empyema the aspirator was essential as a guide to operation. If the empyema was general a needle introduced at any part of the dullest area should find pus, but if it was local and small a prolonged search might be unsuccessful. As many of the localised empyemata occurred in the lung fissures and between the lobes the position of these fissures must be borne in mind. On both sides a line drawn from the spine of the second dorsal vertebra downwards and forwards to the junction of the sixth costal cartilage and rib marked the position of the sulcus which separated the upper from the lower lobe. All above and in front of this line was upper lobe, while all below and behind it was lower lobe. On the right side the position of the second fissure was marked by a line extending from the middle of the first to the junction of the fourth costal cartilage with the sternum. Many of the empyemata which emptied through a bronchus were situated between the lobes of the lung and were located with difficulty. When other attempts had failed a successful exploration could occasionally be made by imprisoning the pus. The patient was directed to empty his chest so far as possible by coughing before retiring to bed. A dose of morphia was then administered and further coughing was forbidden. The aspirator was tried in the morning when the cavity was full. Whilst operating on all varieties of localised empyemata it was essential to keep the aspirator needle in position till the pus had been found. When such an empyema had been discovered the proper treatment was to drain it through the most direct route. A second use of the aspirator was to tide over a temporary difficulty. In a case with urgent pressure symptoms or marked displacement of the heart, or complicated by acute bronchitis, aspiration previous to operation was generally a wise measure. The same principle held in cases of double empyema after draining one side. A third use to which the aspirator could be put was suggested by Murphy of Chicago and if his results were confirmed it would then assume the position of greatest importance. After emptying the chest he injected through the needle a glycerine-formalin solution, and his published results were very remarkable. Mr. Morison said that he had no personal knowledge of this treatment. In adults the danger of general anæsthesia was greater than it was in children because of the condition previously mentioned. Local anæsthesia by infiltration into the skin and muscles was safe and with few exceptions satisfactory if the directions as to the operation he described were followed. With local anæsthesia it was most convenient to allow the patient to sit astride a chair with his arms resting on the back of it. If a general anæsthetic was needed his preference was for chloroform till the patient was insensible, then "open ether" till the finish. The anæsthesia should always be light. The patient should lie on the back and on no account should he be turned on to the sound side. The opening should be made in the axilla between the fifth and eighth ribs. With the patient drawn to the side of the table so that his diseased side projected over the edge Mr. Morison performed the following operation. First the aspirator was introduced, at the sixth interspace by choice. to verify the diagnosis and act as a guide. A vertical incision was made through the skin and soft parts from the intercostal space above to that below the one in which the opening was to be, passing on one side of the needle. A director was then passed along the needle into the pleura and so soon as pus showed in the groove of the director the needle was withdrawn. A closed pair of sinus forceps was next pushed along the groove on the director into the pleura and withdrawn open transversely to the axis of the intercostal space, making a large opening through which a drainage-tube as large as the space would allow was guided along the director into the pleura. It was neither necessary nor advantageous to have the tube longer than two inches; it was best of indiarubber; it should not be perforated where it passed through the chest wall and should always have a safety-pin fixed in its outer end before being introduced. Resection of a rib was sometimes necessarymore often in adults than in children, but quite rarely, he thought, in either, and only in those whose intercostal spaces were exceptionally narrow. Irrigation or other means of cleansing the pleura were not necessary even in feetid empyemata. Many empyemata became chronic because of a superadded infection of the pleura. If the pre-cautions now universally recognised as essential to wound treatment were perfectly carried out from beginning to end chronic empyema would be a rare event. The operation might be satisfactorily accomplished, but much depended upon every dressing, and these could scarcely be too frequently changed during the first 24 hours. It was at this stage that a secondary infection was apt to supervene. The essentials were that every one concerned in the case should have the "antiseptic conscience" and the means for carrying its promptings into effect. These were not obtainable except in a hospital. Even in tuberculous cases a good result might follow proper care. At the end of the fourth day the discharge from an empyema properly drained should be chiefly serous. At the beginning of the third week the tube should be taken out of the pleura, and during this week a director should be passed into the pleura daily to ensure that the outer opening did not close before the one in the pleura. At the end of the fourth week the wound should have healed. If it had not done so, and if there was still a free discharge of pus from the pleura, the case has passed out of the satisfactory stage into the uncertain and serious one of chronic empyema, and the sooner portions of one or many ribs were excised the better. It was well to remember that even after every rib had been excised it was still possible to have a persisting sinus.

Dr. J. S. McCracken dealt with medical points in connexion with empyemata in children and gave statistics from

the Newcastle-on-Tyne Children's Hospital.

Mr. T. G. Ouston spoke upon "Some Surgical Points in Connexion with Empyemata in Children." He said that he did not approve of local anæsthesia for opening empyemata in children owing to the certainty of the child struggling during the operation. Chloroform had given him every satisfaction, but it was not advisable to obtain full surgical ansesthesia; he was convinced that a minimum of ansesthetic was a very important factor. During its induction the patient should lie on the affected side, as a child's chest wall was so compressible that the purulent collection left only one lung available for respiration. The thorax was opened in the eighth interspace, or at any rate well below the angle of the scapula. It was the rule at the Newcastle-on-Tyne Children's Hospital always to resect a portion of rib, as the intercostal spaces in children were too narrow for adequate drainage. The subperiosteal method was always employed. In large and old-standing cases he thought that the periosteum should be removed as well owing to the rapid regeneration of bone. The pleura should be incised with a knife and not punctured with sinus forceps Where the lung was collapsed and its pleura much thickened the prognosis was not good. He had not tried decortication of the lung, but would do so in a suitable case, with an

interval of weeks after the preliminary opening. In cases of non-expansion or only partial expansion of the lung a Wolff's bottle was used for older children and a penny trumpet for younger ones. At the Newcastle-on-Tyne Children's Hospital there had been 100 cases of empyema in seven recent years; of these 67 recovered, 5 were relieved or remained in statu quo, and 18 died.

Mr. JOHN CLAY mentioned the two dangers, early and late, of chloroform, and urged the use of ether as an anæsthetic. He said that the secondary danger, acetone poisoning, was

formerly called septicæmia.

Sir THOMAS OLIVER said that his experience of fœtid empyemata was that they had done quite well. Many years ago his then house physician, Dr. C. M Goyder, elaborated a system of washing out the pleural cavity, but he found mere drainage far more successful. He thought that an atypical pneumonia was often due to the bacillus coli communis—a possibility which was not sufficiently recognised.

Dr. R. S. PEART remarked that no mention had been made of the dull line in the chest, the level of which altered with

the position of the patient.

Mr. A. PARKIN said that he had seen two cases of empyema

associated with malignant disease.

Dr. A. Angus MARTIN mentioned Mr. Rutherford Morison's method of previously making children intoxicated with alcohol so as to minimise the amount of chloroform used for anæsthesia.

Dr. BEATTIE said that he did not think there was any change of level of fluid, as the pleural cavity was like a closed bottle; if, however, the fluids present were of a different specific gravity (e.g., air and serum) the level would then alter with charges of posture.

Mr. G. G. TURNER said that Beck of Chicago had found that by injecting sinuses in various parts of the body with a paste made of 33 parts of bismuth and 67 parts of vaseline even very chronic sinuses could be readily got to heal, and by extending this process to the chest cases of very chronic empyema had been successfully treated. It was essential to use bismuth which was free from arsenic, as some few cases of untoward results had already been recorded.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Specimens. - History of the Teaching of Midnifery.

A MEETING of this section was held on Nov. 5th, Dr. H. JELLETT, the President of the section, being in the chair.

Dr. E. HASTINGS TWEEDY exhibited a specimen obtained from an ordinary Wertheim's operation in a woman about 24 years of age. There was very considerable ulcerative cancer spreading into the broad ligament. The operation went well until he began to remove the cervical part of the nterus. The cancer then broke away, but he was able to shut off the intestines and the woman did not become infected. An interesting feature in the case was that the ureter was not diseased, although the cancer spread above and below it. He pushed the bladder far down into the vagina, got his finger between the vagina and bladder, and was able to dig the ureter completely out of the cancer. That was three weeks ago. The patient had gone on very well until a week ago, when her temperature went up and a feetid discharge arose. Though she could now hold a certain amount of urine in the bladder, still a quantity passed away, and he considered that he was now dealing with a ureteral fistula .- Sir CHARLES BALL (President of the Academy) said that he had once transplanted the ureter into the bladder, and as far as he knew no leakage occurred and no obvious kidney tumour developed.

Dr. R. D. PUREFOY exhibited a specimen of Pyosalpinx, which had reached a very considerable size in a short time, and had arisen under circumstances which made its origin difficult to account for. The patient had been married several years and was childless. She came under his care for a trifling catarrh of the uterus and recovered, as he believed. She was afterwards attacked with severe he believed. abdominal pains and tenderness, and it was then quite easy on palpation to find a tumour having its origin from some of

the pelvic organs. He waited for six weeks before operating. On opening the abdomen a rounded tumour came into view completely concealing the uterus, to which it was extensively adherent. In separating it, to his great distress the sac ruptured and a quantity of pus escaped, but the patient nevertheless made an uninterrupted recovery. There was no ground for thinking the condition to be due to gonorrheal infection, neither was there any evidence of tuberculous disease, but he considered that the case was one of tuberculous salpingitis as the patient's family history was unfavourable.—Dr. Tweedy said that when a tube burst and pus flowed into the pelvis it was largely a matter of chance if the patient would recover. If the pus was septic he knew of no way to avoid the giving of sepsis. If there was any doubt as to the nature of the pus it would, he thought, be safer to cut away the uterus and the tube at the other side; this would have provided a large hole for free drainage, that hole and the vagina being packed with a large quantity of iodoform gauze.—Mr. A. J. HORNE said that in a similar case he had recently adopted the practice recommended by Dr. Tweedy. The patient did very well up to the fifth day, when she complained of pain in the region of the heart, and rapidly sank in a few hours. - The PRESIDENT of the section said that in his opinion it was hardly possible to say positively that the case was tuberculous. He suggested that it originated as an extra uterine pregnancy, and that a hæmatoma formed in it and suppurated.

The PRESIDENT of the section read an address on the Past and Present History of the Teaching of Midwifery. -Sir CHARLES BALL said the questions raised were of extreme importance. As a member of the General Medical Council he had a good deal to say on the whole question, and the chief difficulty experienced by the Council was that of proper hospital teaching. In Dublin they were singularly fortunate in that respect, but some of the provincial towns and even London-were not so fortunately situated, and the principal opposition to the recommendations had come from the licensing bodies, who did not see their way to get such education for their students. Some persons thought that the recommendations should have gone further than they did; but some of them, it could not be doubted, would lead to better education. Those of the Council who were not gynæcologists and obstetricians were very strong on the point that students should be clinical clerks and surgical dressers before taking up practical midwifery, so that they might obtain a reasonable amount of teaching in the practice of antiseptics. The General Medical Council could only make suggestions; but their experience was that while some of the recommendations were unpopular at first they were usually carried out. It had never been necessary for the Council to exercise its power to report the non-adoption of recommendations to the Privy Council, an action which might lead to the degrees of the particular body not being registered. He believed that the recommendations would in time be carried out and strengthened, but they had to move slowly. Dr. F. W. KIDD said that he agreed with Dr. Jellett that a period of six months was one which allowed the student to obtain the necessary knowledge with greater ease than if it was reduced to three months. He thought an alternative might be made with regard to the period spent as an intern in attending a lying-in hospital. A man living inside the walls of a maternity institution saw everything that was going on; he lived in an obstetric atmosphere. If attending as an extern student two nights in the week, whether he saw a case or not, it was difficult for him to devote his attention to lectures next morning. He thought that too little attention was paid to the taking of ample notes of cases either in the house or extern, and it should be the duty of assistant masters or clinical clerks to see that notes were taken and signed by the officer of the institution before credit was allowed for the case. When the question of the clinical examination had first come under his observation he had hesitated as to the feasibility of its being made practical or practicable; but experience had shown him that the difficulties which he had conjured up were to a great extent imaginary. A practical test was quite feasible as regards palpation and the general conditions in the puerperium, and questions could be asked to supplement the history that the student gave. -Dr. Tweedy said that in his opinion it was a hardship on the student to cut down the course of instruction to three months. But there was one safeguard in the

rules that had lately come into force-namely, the rule that a student had to attend 32 times within three months. That rule made it impossible for a maternity hospital to give a three months' course on a one month's residence. -Dr. M. J. GIBSON expressed the view that the period instead of being reduced should be raised to 12 months. But if a man lived in a hospital for one or two months, he would learn far more than from attending twice a week for half a year, and should be spared further attendance.—Dr. Jellett, in reply, said that for the qualified man one month inside a hospital was better than three months outside, but he doubted whether the average student could in the time allowed assimilate what he saw, as he could if the instruction was spread over a longer interval. He was therefore more inclined to agree that the time should be extended to a year. Everyone recognised the practical examination as a great step forward, and the marking should in an entirely new departure be lenient at first.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held in the University on Nov. 11th, Dr. George Wilkinson, the President, being in the chair. - Dr. A. E. Barnes, Dr. Arthur J. Hall, and Dr. H. Leader showed specimens from cases of Hæmorrhage into the Suprarenals. All were bilateral. Dr. Barnes's case showed during life symptoms of intestinal and gastric disturbance. In the stomach there was absence of free hydrochloric acid, but a small amount of lactic acid was present. Connective tissue and undigested muscle fibre were seen in the fæces, as well as a slight excess of fats and soaps. urine contained an excess of glycuronic acid; it also showed a very marked indican reaction, urobilin, and Cammidge's pancreatic reaction. Post mortem there were found atrophy of the gastric mucosa, catarrhal changes in the pancreas, and nodules of lymphomatous tissue in the liver, where the capillaries also contained many lymphocytes. Dr. Hall's case showed during life symptoms of enteric fever, but there was no serum reaction. Dr. Leader's case was a child six days old. Streptococci were found in the kidneys.—Dr. Barnes also showed two large Dissecting Aneurysms of the Thoracic Aorta, which during life had caused acute abdominal symptoms. - The President showed a child with separation of the lateral cartilages of the nose and nasal spines; there was also a slight notch in the centre of the upper lip and between the two halves of the premaxilla. - Dr. Hall and Mr. A. Garrick Wilson showed a man who had had a large hard mass in the abdomen which could be easily palpated and for which a laparotomy was performed. It was thought to be carcinoma of the stomach wall, and as a gastrectomy was impossible, owing to firm adhesions and the presence of numerous enlarged glands in the gastro-hepatic omentum, a posterior gastro-enterostomy was performed. In the course of a few weeks the tumour (which turned out to be inflammatory in nature) entirely disappeared, and the patient's weight increased from 7½ stones to 10 stones 9 pounds.—Dr. A. E. Naish and Mr. Wilson showed a case of cervical rib in a girl. The symptoms were pain in the right shoulder after a long swim and weakness in the right hand and arm. The diagnosis was confirmed by an X ray photograph which also showed a very small cervical rib on the left side. The rib was removed by operation and with the assistance of massage and the constant current the muscles of the hand and arm gradually regained their normal strength.—Other cases and specimens were shown by Mr. W. S. Kerr and Mr. Graham S. Simpson.— Professor Ralph P. Williams read a paper on Open-air Recovery Schools. He reviewed the history of the movement which was first established in Charlottenburg, near Berlin, in 1904, in consequence of an investigation carried out by Dr. Neufert and Dr. Bendix, who showed that of all the children attending elementary schools 7 per cent. were dull and backward, and in half of these their mental condition was due to physical causes such as anæmia, the early stage of pulmonary tuberculosis, bad nutrition, &c. This school, established in the forest, was so successful that the original period of three summer months was extended in the following year to a period from April 1st to Christmas. The Charlottenburg authorities were also about to open a "Forest School" for High School children next year. The parents will pay 80 per cent. and the State will pay 20 per cent. of the ex-penses. Mülhausen in Elsass, Gladbach, Elberfeld, London, ¥ 4

Halifax, Norwich, Bradford, and Sheffield have now established open-air recovery schools. Professor Williams then described the medical and educational arrangements in the Sheffield school. He said that with regard to the selection of children, 50 children suffering from the following physical defects were provided for: Pulmonary tuberculosis, 3; tuberculous glands, 2; anæmia and bad nutrition, 20; oral sepsis, 13; convalescence from acute disease, 2; convalescence after operations, 2; and doubtful cases of pulmonary tuberculosis, 8. The teeth of all the children were examined by Mr. Frank Harrison and the worst cases were operated on. All lessons were taken in the open air except in severe weather, when an old and well-ventilated school building was available. Three good meals were provided and were taken in an open shed facing south. One warm shower bath was provided for each child once a week. The educational work was limited to three and three-quarter hours daily. Each child was provided with a numbered rain cloak, a chair, a blanket, a brush and comb, a tooth-brush, a towel, and a bath towel. Two hours were allowed for rest after the midday meal (90 per cent. of the children slept all the time). The children were weighed every fortnight and the 29 girls and 21 boys increased on an average 2.6 kilogrammes (5; pounds) during the period the school was open—i.e., from June 21st to Oct. 29th, compared with an average of 1.1 kilogramme increase put on by children of the same age attending ordinary elementary schools. The parents contributed towards the expense of feeding the children sums varying from 2s. 6d. to 6d. a week. He hoped that schools of this type would be erected in country districts surrounding all cities, for the recovery and education of ill-nourished children who otherwise would become a burden on their relatives or on the State.

HUNTERIAN SOCIETY.—A meeting of this society was held on Nov. 10th, Mr. T. H. Openshaw, the President, being in the chair. —In the theatre of the London Institution Dr. Alfred C. Jordan gave a lecture on Roentgen Ray Diagnosis for the Physician. The lecture was illustrated by over 80 lantern slides of cases examined by Dr. Jordan. Time being limited, he was obliged to confine himself to diseases of the chest and alimentary canal. Commencing with the heart, the predominant shape of the cardiac shadow in the several varieties of valvular disease was illustrated and explained. Mitral stenosis showed the greatest constancy of form, while that of aortic stenosis was also fairly well defined. In Stokes-Adams disease it was usually easy to count the beats of the auricles and ventricles separately. Pericardial effusion was next dealt with, and the chief points in its diagnosis from a dilated heart were explained. Coming to the aortic arch, it was shown that while there was no difficulty in diagnosing a large saccular aneurysm from an anterior view, in less extreme cases it was always necessary to examine the right anterior oblique view as well, the latter giving a view in the actual plane of the aortic arch. The appearance of the aortic arch in the oblique view, when normal, generally dilated, fusiform, and saccular, was explained by means of diagrams, and a number of illustrative slides were shown. Aneurysm of the innominate artery and descending thoracic aorta was also illustrated. Coming to the lungs, the lecturer dealt first with phthisis, of which disease he had examined close upon a thousand cases during the last three years. He showed that every case with definite physical signs could be detected with certainty by an X ray examination, and the exact extent and distribution of the disease ascertained. Many cases with no physical signs could be similarly detected. The various points of importance in the diagnosis were explained, and the appearance of apical and fibroid phthisis, cavities, bronchitis, emphysema, bronchiectasis, fibrosis, and pneumonia were shown. Fluid effusions in the pleara were next considered, the form when small, moderate, and large being illustrated. The appearance produced by fluid and air in the pleura was shown and contrasted with that of simple effusion. Abscess and hydatid cysts of the lung were shown, and finally the effect produced by new growth in the chest. In examining the gastrointestinal tract from 2 to 4 ounces of carbonate of bismuth might be given without hesitation, in emulsion with sugar of milk and water, or mixed with cornflour or bread and milk. In Germany several patients in whom the subnitrate was used had died owing to liberation of nitrous acid by bacterial action in the bowel. The appearance of strictures of the esophagus was shown, and the lecturer explained how the

bismuth emulsion remained lodged in the dilated portion above the stricture, and a thin stream trickled through and entered the stomach. Esophageal pouches were also shown; in these cases the bismuth emulsion was seen (during the fluorescent screen examination) to pass through the œsophagus in a full stream and to enter the stomach, but a portion remained lodged in the pouch at the upper end. Referring to the stomach, it was shown that the shape of the normal stomach as revealed by a bismuth meal, was not constant, but depended upon the other abdominal viscera which pressed closely upon it, and the amount and weight of the gastric contents. The appearance of the normal antrum pylori in the presence of peristaltic action was explained by means of a diagram, and tracings and photographs were shown illustrating pyloric carcinoma, hour-glass constriction due to new growth, and other conditions. The course of the bismuth meal through the intestines was then followed, and instances of obstruction in the ileum and sigmoid, and dropping of the hepatic flexure and transverse colon were shown upon the screen. The splenic flexure never dropped, being held up by the costo-colic ligament. If a patient with a dropped transverse colon were asked to contract the abdominal muscles the transverse colon was seen to rise to its normal level in some cases. In these cases exercises, massage, &c., might be of benefit by strengthening the abdominal muscles and increasing their tone. rise of the colon (and stomach, which was usually dropped also) was produced by the patient "drawing in the stomach" manual pressure with the flat hand upon the abdomen below the umbilicus often caused the stomach and colon to rise to their normal levels; in such cases a well-fitting belt might be of benefit. Lastly, a case of congenital dilatation of the colon in a baby was shown. The greatly dilated colon was full of gas and showed as a clear, wide band against the rest of the abdomen, which was darker.

PATHOLOGICAL SOCIETY OF MANCHESTER. meeting of this society was held on Nov. 10th, Dr. W. E. Fothergill, the President, being in the chair.—Dr. George R. Murray and Professor J. Lorrain Smith gave an account of a case of Acute Disseminated Cerebro-spinal Myelitis (Encephalo-myelitis). The patient, who was a woman, aged 18 years, complained of failure of vision in the right eye, which became blind in four days. Vision then failed in the left eye, so that she was blind in a week. Then followed loss of power of the left side of the face and of the right arm and leg. On the eleventh day she became deaf. On admission to the Manchester Royal Infirmary she was blind and deaf; her pupils were dilated; there was only slight reaction to light on the right side, the fundus was normal; paresis of the left side of the face and of the right arm and leg was present; the knee-jerks were exaggerated, especially on the right side; anale clonus and Babinski reflex were present on both sides, but more marked on the right; there was apparently no anæsthesia. By lumbar puncture fluid was obtained in excess, but it was normal in character. The temperature was generally subnormal. The patient subsequently lost control of the sphincters and died from respiratory failure a month after the onset of the symptoms. Sections of the spinal cord and brain, stained by Weigert's myelin method, showed irregular areas of myelitis. In the cord in the cervical region the anterior and lateral columns and in the lumbar region the lateral and posterior columns were chiefly affected. The fibres had to a large extent disappeared, and in the more recently affected areas large numbers of compound granular corpuscies were found scattered through the tissue and crowding the spaces of the perivascular sheath. The vessels were engorged but the walls were not thickened and there were no definite signs of thrombosis. An examination for microbes by Gram's method gave negative results. In the optic chiasma and in both auditory nerves recent myelitis was found, and in both cases the fibres had completely disappeared. There was an increase in the neuroglia cells in these areas. Sections from the white matter of the occipital lobe were also shown to demonstrate a myelitic focus. changes in the brain were not so advanced as those in the cord and in the optic chiasma. In the brain the areas affected were visible to the naked eye as small rounded patches of congestion without definite softening.—Professor G. Elliot Smith, in a communication entitled "Disease in Ancient Egypt," gave an account of some of the pathological conditions which he had met with in examining the bodies of

ancient Egyptians. Reference was made to the extreme rarity of tuberculous disease, only 5 cases having been found among more than 10,000 skeletons examined; 4 were cases of spinal caries and 1 of hip disease; the earliest was dated about 3500 B.C. No evidence whatsoever of syphilis has yet been found. Osteo-arthritis was extremely common, but only one case of true gout had been observed and that was a Christian immigrant into Egypt. Dental caries was exceedingly rare among the prehistoric Egyptians, but was quite common among the aristocratic classes in historic times. Cases of mastoid disease (12 in number) were seen, in all of which the pus found a natural outlet in Macewan's triangle. A variety of other conditions, including osteo-sarcoma (3000 B.C.), calculi of the bladder, of the kidney, and of the gall-bladder, talipes, and prolapse of the uterus and rectum, were referred to. - Dr. E. N. Cunliffe described the clinical history and pathological appearances met with in a case of Anzemia with Enlargement of the Spleen occurring in a girl, aged 13 years, and presenting the features, not of splenic anæmia of adults, as is customary at this age, but of splenic anæmia of infancy. A marked feature of the blood picture was the enormous number of nucleated red cells, chiefly of the normoblast type, with a certain proportion of megaloblasts. There were no signs of infantilism such as has been recorded by Cowan in two cases of a similar nature.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Nov. 11th, Mr. T. H. Bickerton being in the chair. - The following specimens were shown: Mr. W. Thelwall Thomas and Dr. W. W. Mackarell: (1) Epithelial Odontome; (2) Exophthalmic Goitre; and (3) Three Epitheliomata from One Lip. Dr. E. Stevenson and Dr. R. E. Harcourt: (1) Melanotic Sarcoma of the Eye (two cases); and (2) Pseudo-glioma of the Eye.—Mr. Charles G. Lee and Dr. Harcourt: (1) Melanotic Sarcoma; and (2) Glioma of the Retina.—Dr. Gordon Gullan: Hour-glass Contraction of the Stomach.—Mr. R. E. Kelly and Dr. Mackarell: Skull and Brain from a case of Pneumococcal Meningitis. - Dr. Ernest E. Glynn: Phagocytosis of Pneumococcus in Cerebro-spinal Fluid.—Mr. Thomas Guthrie: (1) Naso-pharyngeal Fibroma; and (2) Tracheal Tuberculosis. Dr. Nathan Raw: (1) Malignant Streptococcal Endocarditis; (2) Primary Carcinoma of Adrenals; (3) Congenital Cystic Kidneys from a man, aged 44 years; and (4) Tuberculous Appendix.—Dr. J. Lloyd Roberts: Thoracic Aneurysm with Rupture into the Superior Vena Cava.—The specimens were discussed by Dr. T. R. Bradshaw, Dr. N. P. Marsh, Dr. J. Murray Bligh, Dr. J. Hay, Dr. Glynn, Dr. J. H. Abram, and Dr. Harcourt.—Dr. R. J. M. Buchanan read a short paper on Observations on Cytological Methods. He held that as in the body as a whole somatic or systemic death took place the same term is applicable to the death of the cell as a whole, and that systemic cell death takes place prior to disintegration. Recognising the occurrence of death of the individual in instantaneous rigor or cadaveric spasm, he held that cells could die in instantaneous rigor, that this condition is produced and preserved permanently by the most approved methods of instantaneously fixing tissues during life, and that by this means cells could be fixed during any phase of their existence and the appearances coincident with their latest activities permanently recorded. He drew distinctions between cells which were allowed to die slowly prior to fixation. He pointed out the possible fallacies which might arise by the examination of cells in vitro being regarded as equivalent to examination in vivo, and pointed out the danger of the tendency to regard these terms as synonymous in experimental methods. The paper was illustrated by microscopical specimens showing cells fixed and preserved in instantaneous rigor.—The paper was discussed by Dr. G. C. E. Simpson, Dr. Harcourt, Dr. Glynn, and Dr. Abram, and Dr. Buchanan replied.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on Nov. 10th, Professor William Stephenson (Aberdeen), the President, being in the chair.—The President read his valedictory address and gave an account of the lives of some of the honorary and other Fellows who had passed away during his occupancy of the chair, including Dr. C. J. Cullingworth, Dr. C. E. Underhill, and Dr. P. A. Young.—Dr. H. M. Church read a paper on Rheumatoid Arthritis, claiming a puerperal cause for most cases. He gave a clinical record of two cases which he had

studied for 12 years. In one the disease came on after a confinement at the full time, in the other after a miscarriage at the second month. In both the system had been weakened by influenza and shock, which predisposed to a microbic invasion from the genital tract. He pointed out the relation that exists between rheumatoid arthritis and other chronic spinal arthropathies, and conducted his inquiries on the lines recently initiated by the Cambridge Committee appointed for the study of special diseases. Gout, osteomalacia, and rheumatoid arthritis were compared. In regard to treatment, iron taken internally and cataphoresis with iodide of potassium did good. In rheumatoid arthritis a generous diet with butcher's meat was essential and whatever treatment enriched the corpuscular elements of the blood. The retention of phosphorus in the system and therefrom the production of greater hardening of the bones after removal of the ovaries, as shown from experiments upon animals, opened up far-reaching questions. As regards post-mortem appearances, he referred to a case in which 18 months after the onset of rheumatoid arthritis, following a miscarriage, there was found sclerosis of the posterior columns of the cord in the dorsal and of the columns of Goll in the cervical region. The paper was preceded by the exhibition of a metal penholder eaten through by the sweat from the finger of one of Dr. Church's rheumatoid cases, and he thought that the presence of a hypothetic acid, which the American physicians, Dr. Herder and Dr. Baldwin, believe to be pathogenic of the disease (found in the urine in every acute case) might be a factor in the erosion of the metal.—The following officebearers were elected for the ensuing session:-President: Dr. F. W. N. Haultain. Vice-Presidents (Senior): Dr. A. H. Freeland Barbour and (Junior) Dr. J. Lamond Lackie.

Treasurer: Dr. W. Craig. Secretaries: Dr. Angus
Macdonald and Dr. B. P. Watson. Librarian: Dr.
Lamond Lackie. Editor of Transactions: Dr. W. Macrae Taylor. Members of Council: Dr. J. W. Ballantyne, Dr. W. H. Miller, Dr. A. M. Easterbrook, Dr. W. E. Frost, Professor W. Stephenson (Aberdeen), Dr. G. F. Barbour Simpson, Dr. Frederick Porter, and Dr. F. D. Simpson.

Brighton and Sussex Medico-Chirurgical Society.-A meeting of this society was held on Nov. 4th, when Sir Malcolm Morris delivered an address entitled "Certain Important Methods of Treatment about which there is considerable Doubt." He selected the following three points for discussion—vaccines in the treatment of skin diseases, the use and abuse of X rays, and the practical use of radium. As a type of skin disease for which vaccines might be used he mentioned simple local infections of the skin by streptococci or staphylococci, such as sycosis, impetigo contagiosa, acne, boils, and carbuncles. Acne depended on many factors—the anatomical, the coarse rough skin with large sebaceous glands; the physiological, the disease starting at puberty, when many changes take place in the body; the pathological, the altered skin, with reflex disturbance of digestion. Now, he asked, are all other factors except the vaccine to be omitted? No, most certainly all knowledge, past and present, is not to be thrown away. If pustulation is present in a limited area no vaccine should be used. It is only in those cases in which ordinary commonsense treatment fails or is impossible on account of the extent or depth of the lesion, that vaccine from the pus of the patient's own lesions is undoubtedly of value; and the same applied to the various other coccal infections to which he had referred. With regard to X ray treatment of skin diseases there was at the present moment a wave of reaction following on the ' But the proper level of its value would soon be "boom." found. In chronic ringworm of the scalp this treatment meant a cure with absolute mathematical certainty within three months. There was not the slightest shadow of risk with a skilled operator. No single case of injury to the brain has been brought forward and the risk of permanent baldness was so small that it could be ignored. The success of the treatment resulted in an enormous saving in money and time. There were medical officers scattered about who had set their face against it, but they were absolutely wrong in denying the public this enormous advantage. Sir Malcolm Morris also recommended the X rays for old-standing thickened patches of psoriasis, eczema, lichen planus hypertrophicus, pruritus ani, excessive hyperidrosis, chronic sycosis, and breaking-down rodent ulcer or epithelioma. As regards

radium, one broad general rule must be remembered, he said, the action of radium was totally different on skin and on mucous membrane. There was no danger with radium on the outside surface. It produced three effects—a superficial action, a deep action, and a selective action. It was to be used for (a) superficial inflammatory conditions of the skin which defied all known treatment; (b) for port wine nævi; and (o) inoperable epithelioma. Its action on mucous membrane was very different; he did not advise it for advanced cancer of the mouth or tongue, but he would use it if the cancer was quite small and there was no general infection.

CLINICAL SOCIETY OF BATH.—A meeting of this society was held on Nov. 5th, Dr. J. Wigmore being in the chair. - Dr. Rupert Waterhouse showed a case of Rheumatoid Arthritis in a child, aged three years, in whom great benefit had resulted from the administration of large doses (up to three drachms daily) of the syrup of iodide of iron.-Mr. Forbes Fraser showed: (1) a girl, aged 11 years, in the early stage of Macrocheilia and Macroglossia; and (2) microscopical sections from a Sebaceous Adenoma manifesting early malignant degeneration.—Mr. T. McPherson showed a boy, aged 10 years, with a Tumour of the Chest Wall of doubtful nature.—Dr. J. Leckie showed a boy who had four months previously been run over by a bicycle and rendered unconscious for some hours. Recovery took place, but he had returned to hospital with headache and double optic neuritis. -Dr. James Lindsay showed a woman, aged 36 years, with Chronic Disease of the Joints which had started in the great toe-joint at the age of 14 years; the teeth were much ground down and there was persistent albuminuria with granular casts. -Other cases and specimens were shown by Dr. Preston King, Mr. H. G. Terry, and Mr. F. Lace. - Dr. G. H.-H. Almond read a paper on Polycythæmia, which he divided into relative and absolute, subdividing the latter into (1) erythrocytosis, and (2) erythremia. He said that polycythemia resulted from deficient aeration due to chronic lung disease and congenital heart disease. Notes were read describing the case of a youth, aged 19 years, whose blood count showed red cells varying from 9,400,000 to 11,900,000 per cubic millimetre; the amount of hæmoglobin was 145 per cent. and the spleen was enlarged. There was marked clubbing of the fingers, and other symptoms and signs of venous stasis had been present There was increased dulness to the right since birth. of the sternum, and Dr. Almond thought the case was probably one of erythrocytosis due to congenital heart disease.—Dr. J. M. H. Munro read a paper on Various Points in Vaccine Therapy, suggesting from cases observed that pustular acne of the face in young women, without blackheads, the back and chest being clear, might be connected with staphylococcal infection of the blood from accompanying cervical endometritis. He reported a case of so-called carbuncle of the nose due to micrococcus catarrhalis successfully treated by two inoculations of auto-vaccine, and drew attention to the value of tuberculin in certain cases of malignant endocarditis and in persistent chronic nasal catarrh, one case being greatly improved after seven years' previous treatment, including removal of the turbinated bones and draining the frontal and sphenoidal sinuses and maxillary antra ineffectually.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.meeting of this society was held on Nov. 17th.—Dr. C. H. Cattle showed a case of Aphasia with Monoplegic Chorioid Movement.—Dr. A. Fulton, the President, then delivered a presidential address on Medical Ethics. He pointed out that the modern tendency of the Government to create numerous State and municipal medical appointments was becoming dangerous to the profession as a whole, as in many cases the remuneration was quite inadequate and these appointments unduly encroached on the work of the general practitioner. To guard against these dangers we should be united as a whole and first heal our own differences. He then described those "petty jealousies" arising between general practitioners themselves, between general practi-tioners and members of a hospital staff, and finally between general practitioners and the numerous types of consultants which have lately arisen; at the same time he pointed out the proper etiquette to be observed in each case, believing that if only the members of the profession would get to know each other better these differences would soon disappear. An interesting discussion followed.

Reviews and Notices of Books.

Text-book of Embryology. By FREDERICK R. BAILEY, A.M., M.D., Adjunct Professor of Histology and Embryology; and ADAM M. MILLER, A.M., Instructor in Histology and Embryology, College of Physicians and Surgeons (Medical Department of Columbia University). With 515 figures. London: J. and A. Churchill. 1909. Pp. 672. Price 21s. net.

It is a fact that many valuable modern text-books are the work, not of mature senior men who could utilise a life-time of first-hand observation for the enterprise, but of comparatively young men in the first flush of their professional life. The explanation in a subject like embryology is not far to seek. The subject has broadened out so rapidly, and its literature has become so immense in recent years, that it is practically impossible for any individual to possess a first-hand knowledge of all its departments. Enthusiasm, industry, and the assured, unhesitating judgment of youth are needed to systematise in a dogmatic form some of the many-sided and ill-understood facts of modern embryology. young authors of the work under review, taking their courage in their hands, have produced what may truthfully be described as the best text-book of embryology in the English language. It is not stamped with the mark of individual authority like the well-known work of Professor Minot of Harvard, but, on the other hand, it is a most judicious and well-balanced representation of the facts and opinions relating to the development of the body. The authors have shown great judgment in their selection of authorities and of illustrations, and have carried their account up to the most recent researches.

Owing to the predominating influence of Professor Minot of Harvard, and more especially of Professor Mall of Johns Hopkins University, embryology has flourished in the Universities and medical schools of the United States. The methods used in the laboratories and the courses given in the lecture room are copied from Germany. In the preparation of this work the authors have followed closely the German tradition. The first chapter deals with the cell; then follow sections dealing with the genital cells, their maturation, fertilisation, and the production of the embryo. The succeeding chapters treat of the origin and growth of the separate organs and parts. It is a mechanical embryology that is here unfolded, one in which buds grow out, septa spring up, lamina fold over and unite, with seldom a question as to the functional meaning or significance of the phenomena so minutely described. As is the German method, embryology here consists of a detailed catalogue of bare facts unrelieved by the light that can be obtained from the study of comparative anatomy and physiclogy, and scarcely yet affected by the brighter light which experiment is destined to shed on the phenomena of development. The long chapter dealing with the nervous system, where the authors have mainly relied on the researches of His, Elliot Smith, and Streeter, is an exception to this statement, and in that chapter they have greatly added to the value of their description by interpreting facts of development in the light of the facts of cerebral evolution.

Several new features distinguish this text-book. One is a list of "practical suggestions" at the end of each chapter, suggestions as to the manner in which the facts of each chapter may be verified by the student. A list of the most recent papers is given in each section. The differentiation of the various tissues is also dealt with more fully than is usual. On the other hand, although the various malformations of the body are mentioned with the normal development of each system of organs, it is clear that neither of the authors

has first-hand knowledge of these lesions. An appendix giving a clear and reliable account of the technique employed by embryologists is a most valuable feature.

When we examine the size and compass of this work—and it contains only the essentials of the subject—the opinion is forced upon us that embryology, at present a foster-child of medicine, will soon find itself in the position of other sciences that have grown up as foster-children of medicine—botany, zoology, and chemistry—too big to find room enough for development. To work through the "practical suggestions" of this work would take a medical student at least 12 months of constant labour.

The Medieval Hospitals of England. By ROTHA MARY CLAY.

London: Methuen and Co. Pp. 357. Price 7s. 6d. net.

This volume is one of the excellent series known as the Antiquary's Books, published by Messrs. Methuen, and it is worthy in every way of its predecessors. We are quite in accordance with the remark of the Bishop of Bristol, who has written the preface to the book, when he says, "As a book of reference for readers and writers, this treatise on the medieval hospitals of England ought to hold a distinguished place."

The word "hospital" has come to mean in these later days a place practically entirely devoted to the care and treatment of the sick in body. But in early and mediæval times a hospital was, in accordance with its name, a guest house for wayfarers, pilgrims, the poor, the sick, and the infirm. In Oxford were two hospitals which had been founded for the care of the sick as well as for poor and infirm persons. One was the Hospital of St. Bartholomew, founded by Henry I., and the other that of St. John Baptist, founded possibly by King John, but more likely by Henry III. in 1233. The foundation charter is dated 1231. St. Bartholomew's was for "leprous folk," but St. John's was founded that therein "infirm people and strangers might receive remedy of their health and necessity." But the statutes of the hospital lay down very clearly that certain classes of sick folk were not to be admitted. The officer to whom was given the care of the infirmary was the sacrist. He was obviously a priest, for the statutes say that he shall hear the confession of patients before their admission. But he is forbidden to admit the following: "Si fuerint adulti: non admittant (sio) leprosos, paraliticos, ydropicos, furiosos, morbo caduco laborantes, fistulas aut morbos incurabiles patientes nec mulieres lacrimas (sio, but possibly a mistake for 'lascivas') praegnantes nec juvenculas." These rules, it will be seen, excluded a large number of diseases, for the lepers probably included many chronic skin diseases, and possibly syphilis. The paralytics would include a variety of spinal diseases and the hydropics many cases of morbus cordis, of nephritis, of hepatic disease, and very likely solid or cystic abdominal tumours. Cases of epilepsy, fistula, and chronic incurable disorders were also ruled out. The statutes go on to say that such cases were rather to receive an adequate portion of outdoor relief, until such time as they were well. The first patient of whom there is any definite record as admitted to the hospital of St. Bartholomew in London was a carpenter named Alfunyne or Adwyne of Dunwich. He suffered from a general contraction of his limbs, and having heard of various cures wrought at the church and hospital, he came up by sea and was put "in the hospitall of pore men." Here he gradually recovered, power returning first to his hands so that he was able to make "smale workys such as dystaffes" until he became so well that later on he was able to do heavy work, such as hewing wood and squaring timber, together with carpentry work for the church. It will be seen that there is here no definite mention of any surgical or medical treatment.

Miss Clay treats of the various hospitals according to the purpose for which they were founded, as far as possible, for naturally the work of many hospitals overlapped. Thus her first three chapters deal with hospitals for the wayfarer and the sick, for the feeble and destitute, and for the insane. Lazar houses and lepers are dealt with in the next two chapters, and the remaining chapters discuss founders and benefactors, hospital inmates, buildings, management and constitution, their relations to Church and State, and their decline. Finally comes a chapter about the dissolution of religious houses and its effect upon hospitals. The decline of hospitals was due to various causes. Incompetent and dishonest wardens played their part in mediæval times just as they did after the Dissolution or in hospitals founded in post-Reformation times, while as regards leper hospitals, even as early as 1321 a report got about that the lepers had in England, even as their brethren in transmarine parts, "poisoned the fountains of sweet gliding streams" so that "they were utterly hated and their hospitals were for the most part brought to great decay."

Certain hospitals which had fallen from their first estate were merged in other institutions. Thus the Hospital of St. John Baptist above referred to had in the time of William of Waynflete (circa 1456) fallen so low that "it consisted only of a master and four brethren." Its property was ill-managed, its revenues were not spent in relief of the poor, and its rules and statutes were not observed. 1 Its lands and property were therefore annexed to Waynflete's new foundation of Magdalen College, the master and brethren receiving due compensation. Between 1481-5 the hospitals of Romney, Aynho, and Brackley were also annexed to Magdalen College. At the Dissolution, although the Commons proposed that those who entered into the possession of the lands of religious houses should provide for the poor as of old, it only too often happened that as Roderyk Mors remarked in his Complaint, "Your pretense of putting down abbeys was to amend that was amisse in them. It is amended even as the devell amended his dame's legge (as it is in the prouerbe) whan he shulde have set it ryght. he bracke it quyte in peces." The second portion of Miss Clay's book gives an account of hospital patron saints and contains two most valuable appendices, the one being a translation of the office for the exclusion of a leper and the other a tabulated list of hospitals.

We have read the book with extreme interest and can only add our congratulations to those of the Bishop of Bristol upon a careful and excellent piece of work. The value of the book is greatly increased by the illustrations of hospital buildings, seals, and the like.

Probleme der Tuberkulosefrage. Von Dr. JULIUS BARTEL, Privat-dozent und Assistent am pathologisch-anatomischen Universitätsinstitut in Wien. Leipzig und Wien: Franz Deuticke. 1909. Pp. 147. Price M.3.50.

THIS small but important volume is an account of the bearings and significance of the researches on the problem of tuberculosis, which has been carried out during the last few years in Weichselbaum's Institute in Vienna, where Dr. Bartel is principal assistant. The papers on the subject reach a high standard of excellence and deal with certain aspects of tuberculosis which have been too much neglected by the extremists of the contagionist school. The main problems set by Weichselbaum are the relationships of the tuberculosis virus to the organs and tissues of the body, the early changes following the entry of the virus, and the anatomical basis for the doctrine of disposition with reference to the localisation and extent of the tuberculous lesions.

¹ Wilson: History of Magdalen College.

This comprehensive programme has been dealt with in nearly fifty researches, in nearly all of which Dr. Bartel's name appears as one of the authors, mostly in association with Neumann, Hartel, Spieler, and Stein. Almost all these researches have appeared in the Wiener Medizinische Woohenschrift. The general drift and the results of the work have been given by Weichselbaum in his admirable report, "Ueber die Infektionswege der Menschliche Tuberkulose" at the Sixth International Tuberculosis Conference held in Vienna in September, 1907; also by Dr. Bartel in his paper "Leitsätze zur Frage der Tuberkuloseentstehung" the same Congress, and "Zur Frage der Infektionswege der Tuberkulose" at the International Tuberculosis Congress at Washington in 1908. The present book is an expansion of these reports brought fully up to date. Small cheap books of this kind are features of German publishing as compared with English, and they are all the more welcome as they to a certain extent conserve time which is spent in reading through long articles in which even an expert is apt to lose his bearings in the mass of details. Were works like this more frequent there would be much less re-discovery of well-ascertained facts and medical literature would be the less bulky. Even to the specialist a work like this is of importance as it gives the clue to the development of a special line of work by a group of workers, when the particular place in which the full details are can be consulted.

Dr. Bartel's work has aroused much discussion, one point in particular requiring some comment-viz., the doctrine of a pretuberculous or lymphoid stage in the disease. As is well known, the most diverse interpretations are placed upon the lesions of tuberculosis both as to origin and development. There are those who hold that the infection is mainly aerogenic and others who hold it is mainly enterogenic. Having passed an epithelial membrane which is apparently intact, the virus can locate itself in the regional lymphatic glands and give rise to manifest tuberculosis. The Vienna school, however, assert that the virus may locate itself in the regional glands and remain latent for a long period, while no manifest histologically recognisable tuberculosis can be demonstrated. Higher up in the lymph system tuberculous lesions may, however, be apparent and easily determined. If this be so, no accurate deductions can be drawn from ordinary necropsy material as to the path of entry in a given case of tuberculosis, and the extraordinary differences of opinion of even the most expert morbid anatomists support this statement. Apart from evident tuberculosis, there is or may be, according to Dr. Bartel, a pretuberculous or lymphoid stage in which both the histological evidences of tubercle and even the bacillus cannot be seen. Nevertheless inoculation of such lymphoid material develops tuberculosis in animals. This lymphoid stage, which is characterised at most by lymphoid hyperplasia and swelling of the glands, may remain quiescent-latent-for as long as 104 days in experiments. There must be in this hypothesis something in the lymphoid tissue which prevents the bacillus from manifesting its full pathogenic activity. Indeed, considerable evidence is gradually being accumulated on the importance of a histo-immunity as opposed to a humoral-

A large part of Dr. Bartel's work is taken up with the foundations of the disposition to tuberculosis, which is apparently to be sought in the varying resistance of the lymphatic tissues throughout the body. The practical importance of all this work is great, as it may be the means of turning the therapeutics of tuberculosis into new channels which will give a greater chance of success than has been obtained in the past, and for this reason we can recommend the study of Dr. Bartel's small but highly suggestive book.

LIBRARY TABLE.

The Health Resorts of Europe. By THOMAS LINN, M.D. London: Reynold's-Ball's Guides. 1909. Pp. 285. Price 2s. 6d. net.—The fact that this little book has reached its seventeenth edition is a proof that many persons find it useful. It is clearly written, and for its size contains a mass of information. The countries dealt with are Austria-Hungary, Bosnia, Belgium, France, Germany, Great Britain and Ireland, Holland, Italy, Portugal, Spain, and Switzerland. No mention is made of the fairly well-known thermal springs at Piatigorsk in southern Russia some 90 miles N.N.W. of Vladikavkas. Dr. Linn sounds an excellent note of warning in his introductory hints when he impresses upon would-be visitors to a health resort to consult their medical man before going, and not to "take counsel of some kind friend who may have been benefited by taking such and such waters." In a future edition we think that some fuller account might be given of the Bath waters. Except that their temperature is 120° F. and that they contain radium nothing whatever is said about them. But taking it all round Dr. Linn's work is well done.

The Children's Story of Westminster Abbey. By G. E. TROUTBECK. London: Mills and Boon, Limited. Pp. 253. Price 5s. net.—This unpretending little book will make a very good Christmas present for a child or even for an adult. In the words of the preface, its object is "to point out to British children how they may follow the great outlines of their country's history in Westminster Abbey." On p. 4, in speaking of the estates of the ancient Abbey, Mr. Troutbeck mentions Covent Garden and Hyde Park. He might have said that, roughly speaking, the whole of the present S.W. postal district belonged to the Abbey. We doubt if 1 per cent. of the visitors to the Abbey know that there was one Bishop of Westminster. Mr. Troutbeck mentions him at p. 18, but does not give his name. He was appointed by Henry VIII., after that masterful monarch had dissolved the monastery. His name was Thomas Thirlby, and he held the see from 1540 to 1550, when he was translated to Norwich, though Mr. Troutbeck says that he resigned. Among scientific men buried or commemorated in the Abbey Mr. Troutbeck mentions Newton, Darwin, Stephenson, Adams, Joule, Stokes, and others, but he omits John Hunter, whose remains were translated from St. Martin's-in-the-Fields owing to the pious care of Frank Buckland in 1859.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. III., No. 9. October, 1909. Oxford: At the Clarendon Press. Subscription price, 25s. per annum; single numbers, 8s. 6d. each. The contents of this number are: 1. A paper on Leukansemia, by Charles H. Melland, in which a case is recorded and the suggestion is made that if the name of leukanæmia is to be retained it should be more widely applied so as to include all those atypical cases in which there is a leukæmialike condition without any, or with very slight, increase in the number of leucocytes. An interesting discussion of the hæmatological relations of this condition is given, together with a useful bibliography. 2. A Contribution to the Study of Rheumatism, with Notes on the After-history of 25 Cases of Scarlatinal Rheumatism, by F. J. Poynton. Some of the problems in connexion with this disease are discussed and special reference is made to the relation between rheumatism and the arthritis occurring in scarlet fever. Dr. Poynton believes that scarlatinal rheumatism is in many cases true rheumatism. He finds that heart disease is a common event in childhood after scarlatinal rheumatism. 3. On Lymphocytosis of the Cerebro-spinal Fluid in Relation to Tabes, by Judson S. Bury and Albert Ramsbottom. They conclude that lymphocytosis of the cerebro-spinal fluid is not, as has been asserted, a constant phenomenon in tabes and general paralysis, and that although syphilis may play an important part in the production of these diseases it is not an essential factor. 4. On Polycystic Disease of the Kidneys, by Carey Coombs. A case is recorded of polycystic disease in an unpaired kidney, and an analysis of 44 cases is given which shows that in half of them the symptoms of the last phase were those of uramia. 5. An Investigation into the Histological Condition of the Suprarenal Glands in Conditions Associated with High Blood Pressure, by Austin Philpot. He finds that the medulla of the gland is the region involved, no changes being found in the cortex. The medulla was found to be enlarged in nearly every case, and there was a definite increase in the chromaffin substance. In exhausting diseases, on the contrary, the glands were small, the medulla was very narrow, and only traces of the chromaffin substance were present. 6. On the Diuresis of Chill, by Alexander G. Gibson. The diuresis is found to be far too large to be accounted for entirely by diminution of skin loss; it attains its height during exposure, when the cold is severe and prolonged, but is delayed if the cold is not intense or if the exposure is short. 7. Toxic Arthritis, by J. Campbell McClure. This paper contains a study of two types of arthritis-viz., that which occurs after the injection of antitoxic serums and that after scarlet fever. Dr. McClure suggests that the hypothesis put forward by J. R. Currie to account for serum disease—that it is due to the action of some antigen combining with its antibody to produce a poison, and that in those suffering there is an abnormally quick response, so that the amount of poison produced is beyond the immediate eliminative capacity of the individual-may be applied to these two forms of arthritis-8. Some Observations on the Administration of T.R. Tuberculin in Pulmonary Tuberculosis, by David Lawson and H. S. Gettings. They conclude that their observations support the claim made by Latham and his co-workers that tuber. culin administered by the mouth in cases of tuberculosis is absorbed and modifies the blood content, but they do not think that their observations warrant the conclusion that the temperature is a safe and trustworthy guide as to the behaviour of tuberculin in the body. 9. Some further remarks on Leukæmic and Chloromatous Affections by C. H. Treadgold. Four recently recorded cases of chloroma are analysed and are regarded as supporting the views that the bone marrow is primarily affected in chloroma, and that the condition is closely allied to leukæmia. An interesting discussion of the etiology and pathology of the leukæmias is given, and a plea is urged for simplification of nomenclature. 10. The Estimation and Quantitative Significance of Hydrochloric Acid in the Gastric Contents: a Critical Review, by W. H. Willcox. In this important paper the literature of the subject and the various methods of investigation are carefully analysed. Dr. Willcox lays great stress upon the value of determining the "active" hydrochloric acid of the gastric juice-which includes the acid combined with proteins and organic bases as well as the free hydrochloric acid. 11. The Minutes of the Proceedings of the Annual General Meeting of the Association of Physicians of Great Britain and Ireland, held at Dublin.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., ALEXANDER MACALISTER (Cambridge), ARTHUR THOMSON (Oxford), ARTHUR KEITH (London), and ARTHUR ROBINSON (Edinburgh). Vol. XLIV. Third Series. Vol. V., Part I. October, 1909. London: Charles Griffin. Annual subscription, £1 1s. post free.—This number

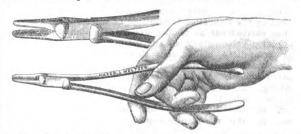

opens with an appreciation of the talent exhibited by the late Professor D. J. Cunningham, and a warm tribute of praise for the valuable assistance afforded by him to the Journal of Anatomy. The scientific contents of this number consist of ten articles, which being usually expressed with clearness and brevity scarcely admit of being abstracted. Their titles are: 1. The Nature and Causes of the Descent of the Testes, by D. Berry Hart, M.D. 2. The Physiological Descent of the Ovaries, by D. Berry Hart, M.D., in each of which memoirs some corrections of the ordinarily accepted description are introduced. 3. The Anatomy of the Palatine Tonsils, by G. Seccombe Hart, F.R.C.S., and H. G. Butterfield, B.A. 4. Obliteration of the Left Common, External, and Internal Iliac Arteries, by A. M. Paterson, M.D. 5. A Cyclopæan Fœtus with Hernia Encephali, by F. W. Watkyn-Thomas, B.A. 6. Abnormal Phalanges in a Human Hand: a case of Brachydactyly, by Walter Kidd, M.D. 7. Congenital Deficiency of a Portion of the Thoracic Skeleton, by T. H. C. Benians and H. Emlyn Jones. 8. A Case of Os Parietale Bipartitum in an Australian Aboriginal Skull, by Richard J. A. Berry, M.B., F.R.S. Edin. 9. Further Observations on the Ossification of the Human Lower Jaw, by Alexander Low, M.A., M.B. 10. Nineteenth Report on Recent Teratological Literature (1908), by William Wright, M.B., D.Sc. In addition, there are some Anatomical Notes and a Report of the Proceedings of the Anatomical Society of Great Britain and Ireland.

Hew Inbentions.

A SIMPLE FORM OF NEEDLE-HOLDER.

THE variety of needle-holders already illustrated in surgical instrument catalogues almost leads one to think that each surgeon needs a special form to suit his individual requirements. Believing, as I do, that anything which favours greater simplicity and uniformity in our operative methods is an advantage induces me to bring under the notice of your readers a description of a simple form of needle-holder which has for several years given me perfect satisfaction and is free from many of the objections unavoidably present in more complicated instruments. Many surgeons avoid the use of any holder where possible, and this has been my invariable custom. For superficial wounds a needle, if straight and of sufficient length, can be used more rapidly and efficiently without any holder, and I usually employ an ordinary straight sewing-needle and thimble for intestinal work, which in most cases can be done outside the abdominal wound. There are, however, many situations in which, owing to inaccessibility or the variety of needle employed, the use of a holder becomes imperative, and it is most satisfactory to have ready to hand an instrument that can be used in a facile and effective manner.

The requirements of a good needle-holder are many: (1) It should be simple in construction; and (2) consequently

easily cleaned; (3) it should be able to grasp an ordinary needle of any form in almost any position without permitting it to rotate and without danger of fracturing it (fracture of a fully curved needle is easily produced by pressing it tigbtly in a holder possessing jaws with grasping surfaces so formed that their approximation tends to straighten the needle); (4) the instrument should be one that can be readily manipulated; and (5) noiseless in action, as

the clicking sound which accompanies the locking and unlocking of many needle-holders is highly irritating to the feelings of a patient who is not under the influence of a general anæsthetic. My needle-holder fulfils the above conditions. Its form and the method of holding it are well shown in the accompanying illustrations. In general appearance it resembles Martin's needle-holder. are, however, much narrower and more pointed. The surface of the lower blade has a broad and shallow grove, while the surface of the upper blade is flat and leaded. This form of construction makes it impossible for the operator to fracture a curved needle even when severe pressure is used in holding it. If the instrument is held in the manner shown in the illustration the ease with which a needle can be released and again seized will be a pleasure to the operator.

The instrument is manufactured by Messrs. Mayer and

Meltzer of London.

C. YELVERTON PEARSON, M.D. R.U.I., F.R.C S. Eng., Professor of Surgery, University College, Cork.

FIRST AID DRESSING "ASEPTO."

The particular merit claimed for this invention, which is to be obtained from Mr. John Voet, 2, Coleman-street, London, E.C., is the facility with which it enables a person, without any assistance or delay, and under most unfavourable circumstances, with dirty and unsterilised hands, to apply an aseptic dressing to his own wounds or to those of others. The dressings consist of compressed pads folded up in an ingenious manner in small and compact packets. Each packet contains one such square aseptic pad attached to two long bandages and so folded that by undoing the bandages the pad can be placed wherever needed and easily tied without any necessity for the person who applies it to touch the inside of the pad with his hands. This method of folding secures the inside of the pad against all contamination and renders it free from any infection whilst the wound is being dressed.

The double packets, which are wrapped in canvas and paper, contain two dressings, to provide against wounds such as bullet or knife wounds, which require the application of a dressing at the points of entry and exit. Yet each packet remains separate, and this makes it possible to use one dress-

ing at a time without opening the other.

The dressing is made so that a wounded person who has only one hand available can easily unfasten it—e.g., with his teeth—tear off the paper wrapping and place the aseptic pad upon the wound. We have examined these dressings in several sizes and can endorse the inventor's claims that they can be applied almost instantaneously with no risk of contamination of the dressing surface. The length of the bandages allows of their ends to be used as a sling if desired. We consider the "asepto" dressing to be a valuable equipment for the soldier in the field. We understand that these dressings, though invented in Holland, are now made in England.

THE AFTER-HISTORY OF LONDON SCHOOL CHILDREN.

The London County Council considered on Nov. 23rd a report by the Education Committee of an important inquiry it has carried out as to the extent to which the scholars at London's elementary schools drift into unskilled labour. The committee claims that this is the first attempt to collect statistics relating to the occupation of children on leaving school. At any rate, its figures are sufficiently striking. Returns made by the head teachers of several hundred schools showed that in 1907-08 33·2 per cent. of the boys who left the elementary schools went to skilled employment, 61 per cent. joined the ranks of unskilled labour, and 5·8 per cent. continued their education at secondary schools. (This last figure takes no account of boys who passed on to secondary schools before reaching the highest standard.) The destination of the girls leaving school was: skilled employment, 58·1 per cent.; unskilled, 34·1 per cent.; higher education, 7·8 per cent. The latter figure, by the way, appears to indicate a tendency no longer to restrict the benefits of an extended education to the boys of the family, as used to be

the case. With regard to the larger proportion of girls who are returned as having obtained skilled employment, the committee mentions that there was considerable divergence of opinion amongst those making the returns as to what was to be considered "skilled" labour in the case of girls. Those who took up domestic service, for instance, were classified as skilled or unskilled according as they went to good positions or were merely employed as "day girls." Another consideration which detracts from the conclusiveness of the statistics is that in many cases frequent changes of employment have been noticed to take place during the first year after leaving school, the children subsequently settling down into some regular, and even skilled, calling. However, after all allowances have been made, the returns show, as the committee points out, that little more than a third of the children on leaving the elementary schools enter a form of occupation which by any stretch of imagination can be called "skilled." The remainder drift into unskilled trades, where they speedily lose the greater part of the mental and moral training instilled at school at such an infinity of time, trouble, This in spite of the fact that London with and expense. over half a million employees in factories and workshops is perhaps the greatest industrial community in the world, and the London child, if efficient, has the best possible opportunity of entering a skilled trade and taking precedence over the new-comers from the country and abroad who eventually constitute one-third of London's population.

A considerable factor in bringing about the state of affairs revealed by the committee's investigations is the unfortunate lack of interest shown by parents of the poorer class in the future of their children. It is a common practice for the children, with only the limited experience of 14 years to guide them, to select their own occupations, and to find for themselves their first situations. They are too young to choose wisely, and they shift from place to place until they discover something that suits their taste and ability. The committee suggested that to render education of more value to the scholars and to equip them to take better positions when they leave school, the age of attendance should be extended to 15 years, and that until the age of 18 is reached attendance at half-time classes should be required. The classes should be attended during working hours, for the experience of many years has shown that evening continuation schools cannot adequately meet the need. The long hours of work and the great distances travelled to and from the place of employment often render attendance impossible, and even where this is possible the boy or girl, after the day's physical exertion, is not always in a fit state to profit by the instruction given. The difficulty of inducing employers to release their employees for attendance at classes is so great that the committee has no hope of the practice becoming general unless Parliament makes it compulsory. The committee would apply a "half-time" system also to the youth of 18, who, after four years of unskilled labour, has lost the intelligence and aptitude of the boy and is on the way to become a clumsy and unintelligent man, fitted for nothing but unskilled labour and likely to become sooner or later one of the unemployed. In the case of girls it is suggested that instruction in domestic subjects should form part of the curriculum at the "half-time school.

In another part of the report (which deals exhaustively with the subject and is to be placed on sale) an account is given of the trade schools which already exist on a small scale in London, and also of the work of the Apprenticeship and Skilled Employment Association, 36-7, Denison House, Vauxhall Bridge-road, which has been largely instrumental in securing the establishment of local apprenticeship committees in 16 districts of London.

The Finance Committee, dealing with the financial aspects of the proposals, estimated the annual cost at approximately £100,000, and expressed the view that unless additional Exchequer grants are made the present is not the time to put forward such drastic and far-reaching proposals.

UNIVERSITY OF LIVERPOOL: ANNUAL DINNER OF LIVERPOOL MEDICAL STUDENTS.—The Liverpool medical students will hold their annual dinner at the Adelphi Hotel, Liverpool, on Saturday, Dec. 11th, at 7.30 P.M. Dr. J. Hill Abram will occupy the chair and Mr. R. Craig Dun the vice-chair.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 27, 1909.

Schools and Infectious Diseases.

An exceedingly useful official memorandum has been issued conjointly by Dr. A. NEWSHOLME, the chief medical officer of the Local Government Board, and Dr. G. NEWMAN, the chief medical officer of the Board of Education-a memorandum which points out, among other things, the way to avoid friction between the district medical officer of health and the school medical officer "when they are not the same officer." The Board of Education might perhaps have been expected to say "when the two offices are not held by the same person," but we have no desire to be hyper. critical, and the words of our old friend the bookseller leave no doubt as to the meaning which they are intended to convey. They are introductory to a careful analysis of the conditions under which the closure of a school, or the temporary exclusion of some of the pupils, may be rendered necessary by the existence of contagious disease, and to recommendations concerning joint action between the sanitary and the educational authorities of the locality concerned. It is pointed out that if the sanitary authority of the district in which the school is situate, or any two members thereof, acting on the advice of the medical officer of health, require either the closure of the school or any department thereof, or the exclusion of certain children for a specified time, with a view to preventing the spread of disease or any danger to health likely to arise from the condition of the school, such requirement must at once be complied with, and the compliance will not involve any forfeiture of the grant; while the school medical officer possesses an equal power of saving the grant in the case of any closure on account of disease by managers acting under his advice or with his approval, although the medical officer of health should not have interwened. There are thus two independent powers, each of which may cause the closure (partial or complete) of a school without loss to the managers; and the memorandum is the expression of the desire of the two central authorities concerned, the Local Government Board and the Board of Education, that the relations between the local sanitary authority and the local education authority should in all respects be intimate and cordial, in order that the administrative procedures of the two bodies may be reciprocally beneficial. It is only, we are informed and can well believe, by such mutual cooperation that the best interests of each district can be secured to the fullest extent.

The memorandum then enters into details with regard to all the principal elements of the questions which the several medical officers "when they are not the same officer" will be called upon to consider and to deal with by united by the representatives of the community. That it is hard

action, and it describes in some detail the chief conditions. and the most important illnesses, by which either the closure of a school or the exclusion of certain children can be required or justified. On all the points thus dealt with its directions are so precise, and so manifestly in harmony with the requirements of the public safety, as to leave very little room for differences of opinion as to the course which should be pursued; and as the duty of the medical officer of health is primarily to secure the safety of the public, while that of the school medical officer is primarily to secure the welfare of the scholars, it is evident that the former will usually be the person who is called upon to take the initiative in the case of any outbreak of disease calling for active interference. The success of his efforts to combat such an outbreak will, at the same time, as far as the action of schools is concerned, be largely dependent upon the goodwill and the cordial assistance of teachers and school authorities; and it is manifest that their attitude in relation to the matter is likely to be much influenced by that of their own medical officer, and by the extent of his approval of the course taken or recommended by his colleague. It is therefore a judicious procedure, on the part of the central authorities, to describe as accurately as possible the conditions which are likely to arise and the action which they will severally require, and in this way to render it difficult for the officials concerned to adopt any other line of action than that which the memorandum prescribes. The course to be generally pursued in respect of each one of the diseases ordinarily epidemic or ordinarily incident largely upon children of school age is explicitly laid down; and except, it may be, with regard to the facts of occurring illness, scarcely any opportunity is left for the display of want of harmony between the officers respectively concerned. It seems hard to dispute that the ideal conditions for efficiency would be those in which these two officers were "the same officer," and in which the several non-medical local authorities were completely shielded against the embarrassment which any conflict of opinion between their respective advisers could hardly fail to produce; but this of course is exactly the point upon which there is a difference of opinion in the medical profession. The memorandum before us evidently takes the view that where possible the two officers should be "the same officer."

We fear, indeed, as a matter of fact, that there is sometimes a considerable tendency on the part of local authorities to seek to neutralise the efforts of their medical advisers by the promotion of something like rivalry between them. The average member of a rural or an urban district council may still regard scientific knowledge with a curious mingling of feeling. He knows it means expenditure against which, as far as he does not understand the reasons, he will continue to strive; but he has apprehensions that, after all, "there may be something in it," and that his opposition to its dictates may produce disaster. He cannot understand the anxiety of medical men to prevent disease; and, as many men can only realise the motives by which they are themselves actuated, he sometimes regards this anxiety as arising from self-interest and therefore to be resisted by the representatives of the community. That it is hard

to explain where the self-interest comes in is a difficulty which in no way shakes conviction of its exist-That the two medical officers should be "the same officer" would often appear to a popular representative of this sort as a condition fraught with peril, if not to the State, yet certainly to the ratepayers, and in his determination to avoid so ill-omened a conjunction he is not unlikely to be strongly in favour of conferring the two appointments upon gentlemen who are suspected of a certain degree of rivalry or of antagonism. There can be no doubt of the absolute necessity for unanimity of action among those of the medical profession who are serving the State in public capacities, or of the importance of the profession protecting itself, by the maintenance of cordial relations between its official members, from the designs of those who would weaken its corporate action by the aid of differences between individuals. That such differences must here and there exist is perhaps unavoidable, but there are regions of activity into which they should never be permitted to intrude. The closure of a school in consequence of an epidemic is an event which has often excited a good deal of strong feeling in the locality concerned; and it is therefore one as to which the medical chiefs of the sanitary and of the education departments are fully justified in calling upon their subordinate officials for unanimity, and in pointing out the lines of action by which this unanimity may most effectually be secured.

The Healer as Prophet.

It is said that a medical autocrat who exercised a professional tyranny over the polite world some hundred years ago once told a young lady whom he had pronounced to be "in a consumption" that she had but two years to live. Being of a contrary nature, however, and having good powers of resistance, on the day when she should have been snug in her coffin the prophet of evil met her out walking and in a positively robust state of health, and as she had not consulted him for some time she hastened to accost him. The physician promptly affected not to see her, and thereafter he passed her always without a sign of recognition, since from his professional point of view she had expired with the period of his prognosis. Absurd as the story is, it serves to emphasise a habit of "cook-sureness" in settling some of the most difficult and delicate questions conceivable that seems to have been not uncommon amongst our professional grandfathers, especially those in the consultant ranks. Possibly some of our readers are acquainted with people who at some time of their lives have been "given so many years to live." Certainly many of those doomed ones are now doing a useful share of the world's work, and in such cases nobody but the stultified prophet has been the worse for his hasty utterance. Most physicians engaged in insurance work have heard of such dicta, but usually in reference to family history, and we are glad to think that medical men are now far more chary in hazarding a measure of their patients' days. Not only has the medical profession realised the appalling responsibility of a hopeless

prognosis, for in no matter is experience more fallacious and judgment more difficult, but it has also come to learn that the counsel of the physician should be one of encouragement rather than of despair, and that, however desperate be a patient's condition, and however importunate he be to know the worst, nothing but harm can result by presenting a full tale of terror to an imagination which in many cases is only too expectant of evil tidings.

In a few special instances, it is true, circumstances may point to the expediency of appraising a patient's expectation of life at his own request, but the power of suggestion over certain physical processes cannot be denied, and in the great majority of cases the formal declaration by one in whom a sick man has confidence as a wise and expert adviser that whatever be done to relieve his urgent distress his days can be numbered with a fatal certainty may have a disastrous effect. There is evidence from the annals of witchcraft that a healthy person believing himself to be persecuted by an occult and evil influence can sicken and even die under a purely psychic oppression; indeed, in our own day the practice of the rites of Obeah in our West Indian colonies has been made a penal offence, because there is no doubtwhatever that the gravest physical consequences have happened to ignorant negroes who believe that they have " had Obi put on them" by a witch-doctor at the instigation of an enemy. This, of course, is an extreme case, but we quote it as showing the ill that can accrue from the force of an authoritative suggestion, and we believe that a medical death-sentence may shorten a sick and anxious man's remaining life. Certainly the physician who pronounces it takes a heavy responsibility upon himself. Even if a man may not arrive at recovery it is surely better that he should continue to journey hopefully towards his end. The question then arises, "Is a medical man ever justified in sitting asjudge and recorder of his patient's days?" We think the justification can be present but rarely. In almost every instance where it is necessary that such warning should be given it can be given to the friends of the sick person, and the medical attendant may very properly discuss with them the advisability of telling the patient of his serious condition. As we have said, an occasional case must arise in which a man whohas been found to be suffering from a mortal malady demands to know the whole truth and gives such reasons for it that the request cannot be refused, painful though it be to reply, but we appeal to common experience that such cases are rare in the extreme. To warn a man that he must be carefulin his exercise or his diet because he has an affection of his heart or kidneys that demands his earnest cooperation in its treatment differs widely from telling him that obedience gives him his only chance of life. If he proceeds to disregard the warning systematically it may become necessary to utter the graver words, but even in such a case the wise practitioner will not attempt to prophesy the length of remaining life. Or it may be the surgeon's duty to tell a woman that she has a growth that will be ultimately fatal if it is not removed, but it is neither expedient nor useful for him toguess how long her pathological condition will allow her

The Schorstein Lecture on "Syphilis and Aneurysm."

THE choice of the Regius Professor of Medicine in the University of Oxford to deliver the Schorstein lecture at the London Hospital was felicitous, and would certainly have been grateful to him in whose memory the lecture was instituted, for the late Dr. Schorstein's devotion to his old university was well known. After a sympathetic reference to his career and its tragic and untimely close, Professor OSLER gave his lecture on the subject of "Syphilis and Aneurysm." The time is ripe for a careful and critical investigation of the part played by syphilis in the production of arterial disease and especially in the genesis of aneurysm, for the discovery by SCHAUDINN of the spirochæte of syphilis, which Professor OSLER acclaims as one of three achievements of the first rank already effected in the twentieth century, and also the recent developments in regard to serological investigations of syphilis by WASSER-MANN have rendered it possible to attack the problem fundamentally. Professor OSLER, in an historical summary, first showed clearly how the acute and almost prophetic insight of some of the great master-minds of the past arrived at the truth, or an approximation to it, in connecting aneurysm with syphilis. Thus Ambroise Paré mentions the association but hints that the mercurial treatment is the cause, while FERNELIUS, MORGAGNI, and LANCISI also definitely described aneurysm as a sequel of syphilis. In spite of these early observations, the connexion between syphilis and aneurysm appears to have been lost sight of until the latter part of the last century, when the general attention directed to the manifestations of visceral syphilis, in which British investigators played no inconsiderable part, once again brought up the question of the relation of syphilis to disease of the blood-vessels. In this connexion Professor OSLER paid a well-deserved tribute to the medical officers of the British army, who, he maintained, first forced the recognition of the part played by syphilis in aneurysm. He referred in some detail to a paper published in 1875 by Colonel Francis H. Welch, then assistant professor of pathology at Netley, which he described as the most important communication on the subject in English. Colonel Welch proved in it the frequency of the association and further recognised macroscopically the form of aortitis now regarded as pathognomonic of syphilis. Previously to this, in 1863, Sir Samuel Wilks recognised the importance of syphilis in arterial disease, and described the characteristic syphilitic arteritis of the cerebral vessels, while Sir CLIFFORD ALLBUTT in 1868 studied the histological changes in these vessels. Professor OSLER also referred to the work on the same subjects by French and German workers and by the Dublin school, including that of TAFNELL. During the past 30 years the numerous researches upon the lesions of the aorta and their relation to syphilis have established the existence of a form of acrtitis found in association with syphilis, which forms the basis of a large proportion of the cases of aneurysm. This form has been described by most recent workers as a mesaortitis. Thus in a paper by Dr. C. U. AITCHISON, published in the second volume of the Archives of the Pathological Institute of the London

Hospital, atheroma is differentiated as a degenerative process characterised by proliferation and subsequent necrosis in the intima and by degeneration in the media, while mesaortitis is described as inflammatory and characterised by round cell infiltration of the adventitia and media with destruction of the muscular and elastic elements. Morbid anatomy and histology could carry investigation but little, if any, further, and it is only in virtue of the new methods rendered possible by the discovery of the spirochete of syphilis and by the serum reactions that the relationship has been proved conclusively. Already numerous observers, including SCHMORL, REUTER, BENDA, and KLOTZ, have described spirochætes in the lesions of the aorta, and Dr. J. H. WRIGHT of Massachusetts has found them in five cases of aortitis, one being associated with aneurysm. The Wassermann reaction has also now been extensively applied in cases of aortic disease and aneurysm, and a positive reaction obtained in no inconsiderable proportion.

It is of interest to notice the special features of the syphilitic aortitis or mesaortitis which forms the basis for the development of aneurysm. Professor OSLER revealed these with characteristic succinctness. Macroscopically the process may be very localised, involving only an inch of the aorta, usually the first part of the arch, and implicating the valves, but it may occur about the origin of the great vessels or in the descending aorta just above the diaphragm. The typical appearance has been described as cicatricial or fibrous aortitis and is characterised by scarring or puckering with narrow linear furrows or little pits with radiating stellate lines. There is also translucency in places due to localised atrophy, giving a bluish tint to some of the depressions. The yellow raised nodules and calcified flakes found in atheroma may be entirely absent, although these lesions may be combined with those of the syphilitic mesaortitis. Microscopically there is necrosis with fragmentation of the elastic fibres of the media, while a cell infiltration separates the elastic and muscular fibres, and extends between the lamellæ in lines, sometimes forming large foci of roundcelled infiltration containing giant cells and areas of necrosis. Miliary gummata may also be found, and the adventitia shows areas of cell infiltration, especially about the vasa vasorum, while many of the smaller vessels show obliterative endarteritis. The changes in the intima are atrophic in places, at others they are those of compensatory thickening. The presence of spirochætes may also be demonstrated. Professor OSLER then discussed the processes by which an aneurysm may develop on the basis of a mesaortitis, whether due to syphilis or to any other infective agency. He described three modes of origin—first, by acute necrosis and erosion; secondly, by splitting of the intima over the weak spot, either spontaneously or as the result of strain or effort; and thirdly, by weakening of the aortic wall, followed by a gradual dilatation. Some interesting statistical considerations relating to aneurysm were given and discussed. Professor OSLER pointed out that about 1 in 459 deaths are returned in England and Wales as due to aneurysm, and that apparently the incidence of aneurysm varies greatly in different countries. He also quoted some interesting figures in regard to the percentage

of cases of aneurysm from which a history of syphilis can be obtained. In 31 cases of aortic aneurysm seen in private in 3 no mention was made of syphilis, while in 10 it was denied, and in 18-i.e., 58 per cent.—there was a positive history. Among 248 cases at the Johns Hopkins Hospital there were 204 cases of aneurysm of the thoracic aorta. Of the total cases there was a well-marked syphilitic history in 40.9 per cent., while the percentage in the thoracic cases was 40.6. In regard to the clinical features of the aneurysms consequent upon syphilitic disease of the arteries, sudden death from perforation of an unsuspected aneurysm is, of course, by no These are, said Professor OSLER, means infrequent. the aneurysms of the third and fourth decades of life, and they often present a triad of features-viz., angina pectoris, aortic insufficiency, and aneurysm, angina pectoris being often the first symptom. The beneficial effects of iodide of potassium, which are noteworthy in the syphilitic form of aneurysm, he held to be especially useful in the varieties presenting this triad of features.

In an eloquent peroration Professor OSLER asked what could be done to restrain the ravages of syphilis, which at a low estimate he maintained to be responsible for 6000 or 7000 deaths annually in this country, without taking into account the unestimated but very large number of stillbirths undoubtedly due to it. He urged in cogent language, first, the wholesome education of youth in matters sexual; secondly, the adoption of measures such as a special police force of men and women to clear the streets and places of public amusement of the open importunities and opportunities for vice; thirdly, that venereal diseases should be put in the same category as other acute infections dangerous to the public health, and each case known should be registered and supervised, though he admitted that such a course might seem visionary and impossible now; lastly, he advocated the increase of facilities for early and prolonged treatment, expressing the hope that the new methods of investigation may lead to forms of treatment which will cut short the disease at its very onset. The occasion of a lecture such as the Schorstein memorial affords an excellent opportunity for some critical observer to call a momentary halt, and as it were report progress on some special point of general interest. Professor OSLER fulfilled this function in a manner wholly admirable, and his lecture was at once an interesting résumé of the present state of our knowledge and an incentive to further efforts in prophylaxis and treatment along the lines which he so eloquently suggested.

THE PREVENTION OF TUBERCULOSIS.—The Tottenham urban district council, on the application of Dr. J. F. Butler-Hogan, its medical officer of health, has granted the free use of the council chamber on Wednesday, Dec. 15th, for the purpose of a lecture on the Prevention of Consumption by Dr. R. W. Philip of the Royal Victoria Consumption Hospital, Edinburgh. As the seating accommodation is limited, early application should be made to the medical officer of health, Town Hall, Tottenham, by medical officers and others wishing to be present on the occasion.

Annotations.

"Ne quid nimis."

THE STANDARDISATION OF DISINFECTANTS.

WE conclude this week the report of our Commissioners upon the standardisation of disinfectants, and from the summary and conclusions which appear in another column our readers will see that a very interesting position has been reached by their work. A method of chemical analysis has been devised which is believed to render a very fair statement of the composition of the disinfectant preparations of the tar or phenolic class which are commonly sold to the public. A bacteriological method has been carefully worked out which gives a truer estimate of the germicidal power of the disinfectant than has hitherto been the case. The chemical and bacteriological results were obtained quite independently and in different laboratories, and when they were brought together certain relationships between them began to appear. Bacteriological figures assigned an order of merit for the various disinfectant preparations examined, and these figures were found to coincide closely with figures founded on chemical considerations. The two sets of figures showed a remarkable parallel. It seems probable that a satisfactory chemical account of a given disinfectant will afford an accurate indication of its germicidal power, but, of course, chemical analysis cannot do more than suggest how far the germicidal agent present is effective under the conditions in which it has to act. As a matter of fact, bacteriological tests, as at present performed, yield figures which convey no real idea of the germicidal power of the agent when it is applied for the purposes of practical disinfection. The figures give merely a comparison, bounded by narrow conditions, between the germicidal power of carbolic acid and that of the disinfectant under consideration, whilst little or nothing is known as to what this germicidal power of carbolic acid amounts to when applied to disinfection under the common conditions of practice. It is conceivable that a consideration of this fact offers some explanation of the remarkable analogy between bacteriological and chemical factors. The bacteriological and chemical activities of an agent appear to be identical powers, and thus under what may be called the ideal conditions of experiment the bacteriological numbers prove to be chemical numbers, and just as the chemical activity of a substance is depreciated by foreign matters so is its germicidal activity reduced. The value for bleaching purposes, to give an analogy, of a solution of chlorine in distilled water may be such that it will effectually bleach a yard of calico, but if the same quantity of chlorine is dissolved in, say, muddy river water, or water polluted with organic matters, its bleaching power may be so reduced as to leave the yard of calico only partly bleached, if bleached at all. The conditions are similar in the practice of disinfection. The question of practical disinfection, in short, is not so easy of solution as is the question of germicidal activity. The work of our Commissioners further indicates lines along which future research must go. Taking into consideration the weakening influence of the environment of every-day disinfecting conditions, they have never been able to find, even under the ideal conditions of bacteriological experiment, such high coefficient figures as have been given to certain disinfectants by other observers, and they are forced to the opinion that many disinfectants have had claimed for them a value, when compared with carbolic acid, which is by no means justified.

SPINAL ANÆSTHESIA BY STOVAINE AND STRYCHNINE.

DURING the visit to London of M. Jonnesco, Dean of the Faculty of Medicine in the University of Bukharest, members of the profession have had an opportunity of observing the latest development of spinal anæsthesia in the hands of its originator. On Friday last, Nov. 19th, M. Jonnesco delivered a lecture before the Surgical and Anæsthetics Sections of the Royal Society of Medicine, in which he dealt with many features of his subject, and we give here a brief account of certain cases at the "Dreadnought," where, through the courtesy of the staff of the hospital, M. Jonnesco was enabled to demonstrate his method. The patients upon whom the method was shown were three in number, and we must say at once that the results did not bear out all the claims made by M. Jonnesco in his published statements. At the same time it is to be remembered that, speaking no English, the operator was unable to gain the confidence on the patient's part of which he is wont to avail himself. To be able to talk to the conscious patient, to reassure him, and to distract his attention are aids to success which M. Jonnesco usually employs, and which were, of course, denied him in the case of patients whose language is unknown to him. Moreover, he had not himself prepared the ingredients which he used for injection, although these were prepared, we understand, exactly in accordance with his directions. Again, he was showing something new to a large and keenly interested gathering of medical men, and it may be that the comparative want of success was due in part to his natural eagerness to show quickly those effects which perhaps would have been obvious if more time had been allowed for their development. The first case was that of a young man requiring operation for a breaking-down glandular mass on the left side of the neck. The patient was a good subject, not nervous or frightened, of healthy colour, and of fair intelligence. Sitting up, he was injected between the first and second dorsal vertebræ with 1 cubic centimetre of solution which contained 3 centigrammes of stovaine and & milligramme of strychnine. After the injection he was kept sitting for about a minute and was then told to lie down, his head resting on a pillow. After about a minute in this position his head was lowered below the level of his shoulders for about half a minute and then placed again on the pillow. There were now some retching and moistening of the lips with the tongue. He was told to turn his head to the right, and all the surgical preparations having been previously made and a piece of lint lightly placed over the patient's eyes, M. Jonnesco at once made the incision. There was no evidence of pain, and it was obvious that the patient was unaware that he had been cut. Vessels were picked up and tied, the same quiet condition persisting. When, however, a little dragging of tissues was necessary to expose glands or to secure bleeding vessels there was almost continuous moaning on the patient's part. In answer to questions, however, he admitted that what he felt was not very bad. The skin suturing caused him no sensation at all. This case, then, demonstrated the truth of M. Jonnesco's assertion that it is possible with perfect safety to inject his solution high up in the spinal canal, and to place the patient in such a position that presumably the solution reaches the brain. There was no evidence of any respiratory paresis, nor of any effect at all upon the medulla, unless the short attack of retching be regarded as such. The colour was well preserved, and the way in which cut arteries spurted showed that there was no depression of circulatory vigour. The skin anæsthesia in this case descended to the level of the middle of the thighs. The corneæ were insensitive to touch, and the arms were paralysed. After-effects were limited to severe headache of some hours' duration. From

the point of view of the surgeon, then, this case, in which the operation lasted about 15 minutes, was during the time of operation almost perfectly successful. The only drawback was that mosning to which reference has been made. On the next case, a laparotomy for gastric carcinoma, the same judgment cannot be passed. Here there was not only groaning but straining expiration which interfered with the surgeon's manipulations to an undesirable extent. In fact, it appeared to us that had a gastroenterostomy been attempted it could not have been carried through with the degree of anæsthesia provided. To what extent the straining was due to sensation of pain on the patient's part we cannot say. It became more obvious when the parietal peritoneum was incised, but it was aroused to some extent by the skin cut too. As there was found a mass of carcinoma in the cardiac portion of the stomach the abdomen was closed. The injection in this case had been made between the twelfth dorsal and first lumbar vertebral spines. In the third case the high injection was made in order to procure anæsthesia for a mastoid operation. After two injections, although the skin was perfectly analgesic there was so much agitation on the part of the patient, a boy, when periosteum was dealt with that chloroform was resorted to and the operation performed under its influence. M. Jonnesco lays great stress upon the importance of not sterilising the stovaine itself. The chemists who prepared the stovaine for this occasion declare that it was not sterilised. Its behaviour. however, suggested to some that in reality there had perhaps been a mistake in this respect and that to this the want of complete success in the demonstration may have been due.

SUMMER MORTALITY IN IRISH TOWNS.

THE Registrar-General's quarterly summary of his weekly returns during the three months ending with September last shows that the annual rate of mortality during this period in the 22 town districts of Ireland, with an estimated population of 1,142,398, was equal to 15.8 per 1000, and exceeded by 4.0 per 1000, or no less than 34 per cent., the mean annual rate during the same period in the 76 largest English towns. This great excess of mortality in the Irish towns is the more remarkable in view of the fact that 16 of the 22 town districts consist of small towns with populations under 14,000, whereas the smallest of the 76 English towns has an estimated population exceeding 50.000. The annual death-rate during last quarter in the six largest Irish towns was equal to 13.1 in Limerick, 14.6 in Belfast, 15:1 in Londonderry, 17:1 in Dublin, 18:5 in Waterford, and 19.0 in Cork; it should be noted that only in Dublin, Belfast, and Cork does the population of these Irish towns exceed 50,000. Even in the 16 small town districts, including two with populations under 8000, the mean annual death-rate last quarter was equal to 14.7 per 1000, which exceeded by 2.9 per 1000 the mean rate in the 76 largest English towns. Infant mortality in the aggregate of the 22 Irish town districts during last quarter, measured by the deaths under one year to births registered, was equal to 139 per 1000, whereas in the 76 large English towns it did not exceed 119 per 1000; it was equal to 143 in Dublin, 152 in Belfast, 136 in Cork, 147 in Londonderry, 117 in Limerick, and 232 in Waterford. In the 16 smaller town districts, however, the mean rate of infant mortality last quarter did not exceed 98 per 1000. The annual rate of mortality from the principal epidemic diseases in the 22. Irish towns last quarter was equal to 2.0 per 1000, while in the 76 English towns it did not exceed 1.6 per 1000; this rate from the principal epidemic diseases in the six largest Irish towns was equal to 1.9 in Limerick, 2.0 in Dublin 2.2 in Belfast and in Londonderry, 3.1 in Cork, and 5.4 in.

Waterford. The mean rate from those epidemic diseases in the 16 smallest town districts did not exceed 0.8 per 1000; of the 585 deaths during last quarter in the 22 Irish towns 390 resulted from diarrhea, 112 from whooping-cough, 28 from diphtheria, and 25 from enteric fever; 358 of the 390 fatal cases of diarrhea, all but one of the 112 from whooping-cough, 24 of the 28 from diphtheria, and 23 of the 25 from enteric fever occurred in the six largest Irish towns. These statistics relating to last quarter make it impossible to doubt that the samitary condition of the largest Irish towns compares very unfavourably with that of the largest English towns having far larger populations. The marked excess of infant mortality last quarter in the six largest Irish towns is the more noteworthy because the general rate of infant mortality in Ireland is, as a rule, distinctly lower than that recorded either in England or in Scotland.

DELAYED POISONING AFTER CHLOROFORM INHALATION.

IN the Johns Hopkins Hospital Bulletin for September Dr. G. H. Whipple and Dr. J. A. Sperry have published an important paper on so-called delayed poisoning by chloroform based on an extensive experimental investigation in animals and on one remarkable case in man. They have arivanced our knowledge a stage. Recent researches have proved that chloroform narcosis in animals for any considerable length of time may in some cases cause central necrosis of the hepatic lobules, and this condition if extreme is fatal. When recovery occurs repair of this necrosis, which may have involved one-half or more of every lobule in the liver, is very rapid, and the organ is restored to normal by absorption of the necrotic cells and multiplication of the remaining cells in two or three weeks. By administering chloroform to dogs for some hours Dr. Whipple and Dr. Sperry induced pathological changes similar to that occasionally observed in man after chloroform inhalation. The animals recovered from the anæsthetic and appeared well, but after a time they began to vomit and sometimes diarrhea occurred. Drowsiness followed and terminated in death after one to four days. mortem examination showed central hyaline necrosis of the hepatic lobules, which was sometimes so extreme as to involve all the hepatic cells except a row or two about the portal spaces. There was fatty degeneration of the cells, which was most intense in the boundary zone between the central necrosis and the intact cells about the portal spaces. There was also fatty degeneration of the kidneys and heart. In some cases small submucous hemorrhages and shallow ulcers, from which there was sometimes much hæmorrhage, were found in the stomach and duodenum. Why the hepatic necrosis produced by chloroform should be central is not easy to say. It is well known that in human and animal pathology central necrosis is common and peripheral necrosis is rare. By prolonged chloroform inhalation the necrosis may be made to extend until every hepatic cell is killed except a row or two about the portal spaces. The explanation of the distribution of the necrosis seems to be that lack of arterial blood or accumulation of waste products in the blood (which flows from the periphery to the centre of the lobule) renders the central cells more susceptible to the poison. Dr. Whipple and Dr. Sperry report the following remarkable case in which they believe fatal delayed chloroform poisoning followed a minor operation. A well-nourished negress, aged 19 years, was admitted to hospital with tuber. culous cervical glands in the neck and right axilla. In the axilla was a lump which discharged pus. Under chloroform abscesses in the chest wall and axilla were incised and

drained. The duration of the anæsthesia was 35 minutes. The patient stood the operation well and rapidly recovered from the anæsthetic. But vomiting began in the night and continued on the following day, when there were muscular tremors in the arms and legs, delirium, and slight jaundice of the sclerotics. Convulsions and coma followed, and death occurred at 6.40 P.M. The urine contained a trace of albumin and a few hyaline casts but no acetone. The necropsy showed extreme central necrosis of the hepatic lobules and fatty degeneration of the kidneys and heart. It is stated that ether anæsthesia causes similar visceral changes, but this is denied by Lengeman and others who have found that even prolonged anæsthesia causes no damage to the viscera. It has long been recognised that chloroform, like many other poisons, will, under certain circumstances, produce certain pathological changes in the organs concerned in the metabolism of the body. It has been shown pretty conclusively that chloroform is only one of many factors which are concerned in producing these changes. In many of the cases which have been published such extremely small quantities of the anæsthetic have entered the circulation that no doubt can be entertained upon this point. The original workers in this field-Thiene, Fischer, and Strassburg—demonstrated that concentrated doses of chloroform, when given for a long time or repeated within short intervals, cause the curious lesions to which Dr. Whipple and Dr. Sperry refer, but it is all-important to recognise that chloroform in appropriate percentages does not necessarily cause them. It may do so if other contributory circumstances exist, but the fact remains that of the thousands upon thousands of persons who have inhaled chloroform the large proportion have done so without developing acidosis and degenerative changes in the liver. Research in this direction appears to prove the danger of chloroform in concentration and to emphasise that its safety lies, not only in avoiding the classic dangers of respiratory failure and undue fall in blood pressure, but also in restricting the quantity employed to the bare needs of anæsthesia. Deep and prolonged narcosis carries with it the danger of chloroform toxemia, the destruction of the protoplasm of certain organs of the body, and our present knowledge, due largely to the work of Professor Moore and Dr. Roaf, explains how this destruction may be brought about. We know also that deep narcosis is seldom, if ever, needed in surgery, and certainly need never be greatly prolonged. It would be matter of regret if such work as that of Dr. Whipple and Dr. Sperry were read to mean that chloroform as such possessed intrinsic and uncontrollable toxic properties; to us it seems rather to add one more argument in favour of using chloroform in a scientific manner and by definite doses.

SCIENTIFIC CHILD-STUDY.

WE have received a letter signed by Professor J. J. Findlay, President of the Child-Study Society, and Sir Edward Brabrook, its chairman, saying that the council of the society in its effort to place its work on a scientific basis has approached Professor Karl Pearson, F.R.S., who with his laboratory at University College, London, is in a position to render exceptional service. Professor Pearson has drafted a schedule for studying the factors influencing the social life of the child, which he desires to have filled in by heads of families or by teachers intimate with families. number in the family need not be large, but particulars of father, mother, and at least two children are required. It is considered more important that the schedule should be filled up for families of the upper, middle, or professional classes. The schedules are being distributed through the branch

secretaries of the society in London and in other large centres, and we suggest that our readers might assist this work by applying for a copy of the schedule and taking the trouble to fill in the particulars, for either their own families or those of friends who would give their intelligent and sympathetic cooperation in the inquiry. The schedule is ingeniously contrived to elicit a large amount of information concerning the parents' qualities and aptitudes, as well as touching the characteristics of the children, regarding whom the inquiries concern their health, upbringing, education, tendencies, and modes of living, work, and play, sufficient to afford a fair summary of their psychological development. The correlation of a large number of these charts will entail an enormous amount of work, and it is to be hoped that only those will apply for them who are prepared to fill them up with painstaking accuracy. The proper preparation of one schedule would probably take two or three hours' careful consideration. The council states that parents who would prefer that the actual names of their family should be withheld can fill up a copy of the schedule on that understanding, supplying their name solely to the secretary, who issues the copy with a key number. Copies can be obtained from the Secretary of the Child-Study Society, 90, Buckingham Palace-road, London, S.W.

THE DOCTOR OF DICKENS'S DAY.

Mr. G. W. E. Russell contributed a whimsical article to a recent issue of the Manchester Guardian, in which he contrasted the family physician of 50 years ago with his successor of to-day, claiming as his justification that he was in his own person a monument of medical practice, having "not only seen, but felt," the rise and fall of several systems of surgery. Broadly speaking, he said, the doctors of the "fifties" and "sixties" were as Dickens drew them, the doctor who was called to the bedside of Little Nell, and came with "a great bunch of seals dangling below a waistcoat of ribbed black satin," being a most carefully finished portrait. Such, exactly, were the family physicians of Mr. Russell's youth. They always dressed in shiny black-trousers, neckcloth, and all; as a class they were bald, and though they shaved their lips and chins they wore carefully-trimmed whiskers. They said "Hah!" and "Hum!" in tones of omniscience which would have converted a Christian Scientist; and, when feeling a pulse, they produced the largest and most audibly-ticking gold watches known to the horologist's art. They had what were called "the courtly manners of the old school"; were diffuse in style, and abounded in periphrasis. Thus they spoke of "the gastric organ" where their successors talk of the stomach, and referred to brandy, in which they placed whole-hearted faith, as "the domestic stimulant." The brandy treatment, remarks Mr. Russell, whatever havoc it wrought on a patient's nerves, digestion, and circulation, conferred on him the advantage that when he grew to man's estate and passed from "that poor creature, small beer" to the loaded port and fiery sherry of a "wine" at the university it was impossible to make him drunk. He had, in fact, become quietly immunised. By no violent transition, but gradually and imperceptibly the medical profession has transformed its members into the type of to-day. It was not till the "seventies" were well advanced that the change became apparent. "The present doctor," says this critic of manners, "is as polite and gentlemanlike a young fellow as one could wish to meet," but his behaviour is not "courtly." He does not bow when he enters the room, but "shakes hands and says it's an Al day and I had better get out in the motor." He has abandoned the majestic "we" which formerly the faculty shared with kings and editors. "We

shall be all the better when we have had our luncheon and a glass of sherry," said Sir Tumley Snuffim. His successor says: "Do you feel as if you could manage a chop? It would do you pounds of good"; or "I know the peroxide dressing is rather beastly, but I'd stick it another day or two if I were you." Medical conversation, too, is an art that has greatly changed. "Tom Guy" (not an individual but a type) does not "lubricate" an interview, as his predecessor did, but goes straight to business-inquires, examines, pronounces, prescribes-and then, if any time is left for light discourse, discusses the British thoroughbred, or the rival merits of the two games of football, or delivers an emphatic verdict upon the latest play. Far otherwise did Dr. Parker Peps regale Mrs. Dombey, or Sir Tumley Snuffim soothe the shattered nerves of Mrs. Wititterly, and some may think that though we have discarded, and rightly, their charlatanism, we should be none the worse for some of their impressive demeanour, which assuredly had a suggestive influence.

ABDOMINAL CRISES IN DIABETES.

In the Intercolonial Medical Journal of Australasia for September Mr. R. M. Downes and Dr. R. A. O'Brien have reported two cases of diabetes in which an abdominal crisis occurred suggesting to three or four observers the necessity for operation. In the first case a well-nourished boy, aged 14 years, was admitted to the Melbourne Hospital in the early morning as a case of acute intestinal obstruction. His father stated that at 6.30 A.M. on the previous day he vomited and that he seemed unwell during the rest of the day. Towards the evening he complained of pain extending across the lower abdomen. This pain had increased up to the time of admission. For 36 hours neither fæces nor flatus had been passed, though the boy attempted to go to stool several times. Vomiting occurred three or four times during the day. About two hours before admission he became very restless with a vacant expression. He became duller, so that on admission he was only semiconscious and unable to answer questions rationally. He had suffered from diabetes mellitus for 18 months. His abdomen was prepared for laparotomy, an enema was given with only a small result, and he was put on the table. He was very restless and uncontrollable. The temperature was 99° F. and the pulse was 160. The abdominal muscles were board-like all over; this was thought possibly to be volitional. Abdominal respiratory movement was absent; there was moderate distension and apparently some tenderness. Both flanks were dull. On the right cheek was a large furuncle. The tongue was dry, brown, and coated, and the face was flushed. Mr. G. A. Syme was about to operate when it was found that the urine contained a large quantity of sugar and gave the ferric chloride reaction for aceto-acetic acid. He therefore did not proceed. Sodium bicarbonate was given by rectal and intravenous injection and by the mouth. The bowels acted slightly. At first the patient improved but later the coma increased and he died on the following morning. At the necropsy the gastro-intestinal tract was found normal. The pancreaswas atrophic and firm. In the second case a girl, aged 8 years, was admitted to the Children's Hospital, Melbourne, on Dec. 1st, 1908. She was suffering from glycosuria which disappeared under strict diet. On the 14th she was well and the urine contained no sugar, diacetic acid, or acetone. On the 15th she vomited. several times and complained of paroxysms of abdominal pain. The urine contained diacetic acid and a trace of acetone. A high enema was given and was followed by a motion. In the evening she complained of pain over the right kidney which extended towards the labia. At 5 A.M.

on the 16th there were paroxysmal abdominal pain, constant vomiting, a pulse of 140, and a temperature of 99.4° F. The abdomen was generally tender and was dull to deep and light percussion below a convex line passing from the anterior superior spines of the ilium through the umbilicus; it was resonant in the flanks. The upper abdomen was slightly distended and the liver dulness was much diminished. There was no rigidity or lessened respiratory movement. The leucocytes in the blood numbered 50,000 per cubic millimetre. Acute intestinal obstruction causing auto-intoxication and acetonuria was diagnosed. She was seen by Dr. Maclaren and Dr. Cole, who concurred in the diagnosis and the necessity for operation. At 10 A.M. the pulse was 172, the temperature was 99.60, there was incessant vomiting, and the abdominal signs were unchanged. But at 10.15 the abnormal abdominal dulness had disappeared and the child was semi-comatose. An abdominal crisis of unexplained origin in a diabetic subject was diagnosed. Bicarbonate of sodium was given by intravenous injection and by the mouth, and after 18 hours the urine became alkaline. Next morning she was bright and played with toys. The diacetic acid and acetone disappeared from the urine in ten days, but sugar returned on relaxing the diet. Similar cases do not appear to have been reported previously, but Grube has described in diabetes attacks resembling the gastric crises of tabes. The nature of the cases now recorded is obscure, but they show the necessity of examining the urine not only for sugar but also for diacetic acid and acetone in all acute abdominal cases. In the second case sugar was absent, though acetonuria was present.

LARYNGEAL TUBERCULOSIS.

WE have received a communication from Dr. Beverley Robinson drawing attention to the valuable information which may be derived from an examination of the larynx in cases of doubtful diagnosis of disease of the chest. He states that he has been able to make a positive diagnosis in this way, not merely of the intra-laryngeal condition, but also of that of the lungs. He further says: "I am confident that no physical exploration of the chest, no tests by means of tuberculins, or with the X rays, or by any other known method will afford in previously doubtful cases as much desirable and accurate knowledge to affirm positively a diagnosis as what is revealed to the experienced eye by means of the laryngeal mirror." Dr. Robinson is evidently an enthusiast on this method of examination. Whilst fully recognising his personal dexterity and knowledge of laryngeal conditions, we would point out that but comparatively few practitioners are able to obtain the experience necessary to enable them with unerring accuracy to make a diagnosis such as Dr. Robinson suggests. He forwards to us an article entitled "Clinical Notes on Laryngeal Tuberculosis," written by himself, which appeared in the American Journal of the Medical Sciences for August, 1908, in which this subject is dealt with in more detail. Attention is here drawn to the fact that the voice may be almost, if not entirely, normal at times, and yet there may be inactivity or slight paresis of one or both vocal cords: or there may be marked localised anæmia; or there may be slight congestion of one or both vocal cords in a limited area; or the arytenoids may be slightly infiltrated, and likewise the interarytenoid commissure. Robinson insists that these appearances are suspicious; indeed, he says, with a certain history they are more characteristic even than a little prolongation or harshness of the expiratory murmur at the apex of the lung or an indefinite dulness, "which is often nothing more than the result of the percussion note elicited by a finger from a relaxed or possibly corpulent chest wall." Dr. Robinson's remarks are certainly is applied to the affected testicle with the patient standing

interesting and worthy of close attention, and doubtless examination of the larvnx is not practised as much as it should be in suspicious cases of diseases of the chest.

THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Council of the Royal College of Surgeons of England has added a special room to the museum for the display of various exhibits of historical interest. These were formerly scattered in different parts of the museum but have now been brought together by the museum committee and form a unique collection of interesting exhibits; many of them have not hitherto been on view. They include the body of the wife of one Van Butchell, which was embalmed by Dr. Cruikshank and William Hunter in 1775; the mummied body of a boy who died from plague in 1665, which was found in the crypt of St. Botolph's Old Church; the skin of the heads of three Macas Indians from Ecuador curiously preserved so as to contract to the size of a doll's head and at the same time to retain the features of a living individual; a collection of boots, shoes, and gloves worn by the Irish giant O'Brien; pieces of human skin which had formerly been found nailed to the doors of Worcester Cathedral and the churches of Hadstock and Copford in Essex; a chain and belt formerly used for the purpose of securing lunatics; a cast of the head of Deeming the murderer, who was hanged at Old Newgate in May, 1892; and an electrical machine used by Surgeon Birch about 1775, with a manuscript copy by his sister describing the cures said to have been effected by him with the machine. This makes an extraordinary ethnological cabinet.

BIER'S METHOD IN ACUTE GONORRHŒAL EPIDIDYMITIS.

In the Boston Medical and Surgical Journal of Oct. 28th Dr. J. D. Barney has called attention to the value of Bier's method in acute gonorrhœal epididymitis. In some recent books strapping the diseased testicle with a piece of rubber bandage secured by a strip of plaster is recommended. A piece of thin rubber bandage about 8 inches long and 4 inches wide is used. To the middle of one end is stuck a piece of adhesive plaster 4 inches long and ½ inch wide. The bandage is drawn round the testicle to the proper degree of tightness and is secured with plaster, which must be placed above the greatest diameter of the testicle, otherwise the apparatus will slip off. It is said that if the directions are followed the bandage lies smoothly over the testicle, free from wrinkles, like the cover of a tennis ball. But Dr. Barney finds that it is impossible to attain this end with a single strip of plaster. The loose and elastic scrotal skin allows no such nicety of application, and the apparatus becomes rolled into a narrow strip at the base of the scrotum or slides downwards and falls off. By using two strips of adhesive plaster instead of one Dr. Barney has succeeded in making the plaster lie smoothly and tightly over the whole testicle. The piece of rubber described in the books he finds too short and much too narrow. The dimensions should be about 9 or 10 inches long and 6 inches wide, being altered to suit the size of the testicle. Neither strip of plaster should be long enough to meet completely round the testicle. This would produce a firm unvielding band which when the scrotum swells might be harmful. An interval should be left between the ends of each strap so that the swelling may proceed with only the vielding rubber to check it. The degree of tightness with which the bandage is applied is largely a matter of experience and of experiment in the individual case. If properly applied the bandage should cause no pain. The bandage

and is secured at the upper end with one strip of plaster. When the scrotum is released after the application a few wrinkles are bound to occur. These are obliterated by pulling downwards the free lower edges of the bandage. These edges are next approximated and overlapped more or less, so as to produce a snug fit, and are fastened by the second piece of plaster, which must be applied below the equator of the testicle; otherwise the whole apparatus will slide upwards. The whole testicle is thus enveloped in a smooth, tight, rubber bag, and a suspensory bandage is applied. As the apparatus causes profuse sweating the scrotal skin should be watched carefully for maceration or excoriation. is prevented by a liberal coat of dusting powder applied daily before the bandage is readjusted. In the first 24 or 48 hours there is usually marked cedema of the scrotum with moderate cyanosis. The epididymis may show more induration and more enlargement, but it usually may be palpated with little or no discomfort—a great change from the previous extreme sensitiveness. The bandage may be applied even to the most tender testicle, but patience and gentleness are necessary. In the majority of the cases treated immediate and permanent relief was given. Patients scarcely able to walk because of the painful and tender testicle could walk easily and without pain and in most cases could resume work. The apparatus should be worn constantly, but readjusted daily until all acute symptoms have subsided and the induration and cedema have disappeared. This period may vary from a day to a week, after which the suspensory bandage alone should be worn until recovery is complete. Dr. Barney concludes that for the ambulatory treatment of epididymitis Bier's treatment is the most valuable method, but, as under all methods, there are occasional failures.

LEADLESS GLAZED CHINA AND EARTHENWARE.

THE beautiful specimens of leadless glazed ware which were exhibited this week at the Caxton Hall, Westminster, must have done much to remove from the minds of the visitors the impression that lead was an indispensable æsthetic constituent of pottery. In addition to numerous specimens of table and toilet ware, both of the inexpensive and finest kinds, examples of ornamental pottery and porcelain, artistic tiles, cooking utensils, fireclay, and other sanitary ware were shown. Determined to be practical, the organising committee arranged an exhibition illustrating the durability of the leadless ware, and submitted for inspection pieces of ware guaranteed to have been in constant use during a fair period of trial. The exhibition afforded us particular gratification, inasmuch as we got practical proof that lead could be abolished in the pottery trade for most practical purposes ten years ago, the report of our Commissioner appearing in THE LANCET of Jan. 7th, 1899. In spite of the adverse criticism which that report received we have now before us ample evidence that the cause of leadless glazes has considerably advanced, to the welfare, of course. of the operatives concerned in the pottery industry. Leadless glazed ware is now a practical success in most, if not all, directions.

MULTIPLE DIVERTICULA OF THE SIGMOID.

It is quite remarkable how a pathological condition at one time regarded as excessively rare is found to be of no unusual occurrence when once attention has been directed to it. Very few cases of multiple diverticula of the sigmoid loop of the colon had been observed in this country until the appearance of a remarkable paper by Dr. W. H. Maxwell Telling which we published some time ago. 1 Dr. Telling was

1 THE LANCET, March 21st, 1908, p. 843.

able to collect 80 cases and from the attention which this condition has received from pathologists on the continent in recent years one must infer that it is frequently observed abroad. The condition, although occurring most frequently in the sigmoid colon, may be found in the descending colon and also may extend to the small bowel. A multitude of small hernise of the mucous membrane, varying in size from a pea to a walnut, become extruded on the surface of the bowel—often within the appendices epiploice or the attachment of the mesentery. The cause of the condition is most obscure. The subjects of it are usually over 50 years of age and are often very fat. Dr. Telling found that the condition gave rise to no symptoms in a large proportion of cases. In other cases perisigmoiditis occurs.

THE Lord Lieutenant of Ireland has appointed Sir William John Thompson, M.D., to be Registrar-General of Ireland in place of Sir Robert E. Matheson, LL.D., whose term of office expires on Dec. 1st.

PLAGUE is still increasing in Mauritius. A telegram from the Governor to the Secretary of State for the Colonies has reported 56 cases with 27 deaths during the week ending Nov. 19th.

Looking Back.

FROM

THE LANCET, SATURDAY, Nov. 26th, 1881.

SPEEDY PASSAGE OF A PIN.

A young lady, while changing her dress, put some pins into her mouth, one of which she swallowed. The pin stuck in the exophagus, but could not be seen or felt. She was greatly terrified and complained of acute pain behind the trachea, and said "the pin was making its way through." I forced it into the stomach with a probang, and she became at once relieved. Previous to my arrival at the house, her sister had given her a dose of castor oil, which affected the bowels freely the following morning, and the pin passed through the intestinal canal in fourteen hours from the time of the accident!

There is necessarily great alarm excited by the occurrence of such accidents, accompanied by great anxiety on the part of the patient and friends with respect to the constant administration of purgatives; but in my opinion, it is better to watch the case closely and combat any untoward symptom that may arise, and leave the rest to nature. (A case contributed by Richard Corbett, M.D., Inneshannon, County Cork, dated Nov. 3rd, 1831.)

Philo-Medicus complains of the great hardship and injustice towards the apprentices of apothecaries and chemists and druggists from the practice, now so generally pursued, of keeping the shops open until 11 and half-past 11 o'clock at night; and he recommends that there should be a general arrangement between the masters to close the dispensaries and shops at an earlier hour, in order that assistants and apprentices might have sufficient time for study and rational recreation. If such an arrangement nere entered into, the spirit of competition would quickly dissolve the bonds of such a union.

ROYAL METEOROLOGICAL SOCIETY.—At last week's meeting of the Royal Meteorological Society the President announced that the council had awarded the Symons gold medal to Mr. William Napier Shaw, D.Sc., F.R.S., in recognition of the valuable work which he has done in connexion with meteorological science. The medal will be presented at the annual general meeting of the society on Jan. 20th, 1910.

THE STANDARDISATION \mathbf{OF} DISINFECTANTS.

WITH SPECIAL REFERENCE TO THE DISINFECTANT PREPARATIONS COMMONLY SOLD TO THE PUBLIC.

A CHEMICAL AND BACTERIOLOGICAL INQUIRY.

SECTION III.

GENERAL SUMMARY AND CONCLUSIONS.

PART I .- Chemistry.

WE have now recorded the chemical composition of a number of tar disinfectants as determined by what we have called THE LANCET Acetone-Baryta method (L.A.B.). And we have also presented the results of bacteriological examination conducted under conditions of laboratory practice 2 (Table XXIV.3). Before we discuss the question as to how far we are able to apply these results as a basis of calculation to practical conditions of disinfection, we may first refer to an interesting relation which appears to exist between the carbolic coefficients found by bacteriological experiment and certain chemical factors. In Table I., published in the first section of the report which deals with the chemical analysis of disinfectants, col. 1 contains the percentage weight of phenoloid body found, while col. 2 gives the carbolic equivalent of this weight according to bromine value, reckoning that 94 parts by weight of carbolic acid correspond to 480 parts by weight of bromine in accordance with the equation, $C_0H_0OH + 6$ Br = $C_0H_2Br_3OH + 3$ HBr. In Table XXV. the weight of phenols (col. 1) and their bromine value (col. 2) in terms of absolute carbolic acid are reproduced. In the same table the mean carbolic coefficients determined by bacteriological experiment in which the bacillus coli was the organism chosen are given in col. 5.

TABLE XXV.

						
	1	2	3	4	5	
Disinfectant.	Phenois or phenoloids (P).	Carbolic acid equiva- lent by bromine (B).	Br. equivalent deducted from actual weight of phenol (P-B).	P-B 3	Carbolic coefficient (bacillus coil), mean.	
Cofectant	66.27	38-30	27:97	9:30	9.8	
McDougall's M.O.H. Fluid	47.13	22.71	24-42	8.1	7.9	
Kerol	40.56	17-23	23.33	7.7	7.7

Zotal	10.00	6.70	3.30	1.1	1.5	
Jeyes' No. 2 (Grocers')	5.13	1.87	3.26	1.0	0.75	

It soon appeared that as the difference between the figures in col. 1 and col. 2 widened so the carbolic coefficient found

by bacteriological experiments was higher. that if the phenol body present in the disinfectant should be carbolic acid itself, the bromine value (col. 2) would be identical with the weight of phenol found (col. 1). As will be seen such was never the case, and so the conclusion is reached that none of the disinfectants examined contained carbolic acid.

If next the percentage bromine value in terms of carbolic

acid is deducted from the percentage weight of phenoloid bodies found, a series of figures is obtained which produce, with few exceptions, the order of germicidal values as determined by bacteriological experiment. The chemical figures, at all events, agree with the bacteriological figures as to differentiating the feeble from the strong germicidal preparations. When further these results are divided by a common denominator—e.g., 3—a quotient is obtained which coincides in the majority of cases with the carbolic coefficient found when the bacillus coli was selected as the organism in bacteriological experiment. Possibly with another denominator a formula might be obtained giving the carbolic coefficient for any organism. In the present examples the formula $\frac{P-B}{3}$ gives the carbolic acid coefficient for bacillus coli, in which P is the actual percentage weight of phenol bodies found and B the percentage of carbolic acid found, calculated upon the amount of bromine absorbed. On the face of these results the bromine value of a phenolic body under the conditions of experiment would appear to be an index of its germicidal power, and the carbolic coefficient, whether it is found by chemical or bacteriological processes, comes to the same figure. are, however, apparent exceptions to this formula if we consider the examples of crude carbolic acid—"Calvert's No. 5 Carbolic Acid," "Lysol," and "Lawes' Fluid" given in the table (XXV.). But it is certainly remarkable that these preparations, which form the exceptions, do not produce emulsions with water in the way that the rest do, and the solutions do not exhibit the Brownian movement. It is also remarkable that in these exceptions the formula P-B gives an indicated value approximately double that 3

found by bacteriological experiment. In these cases it would appear, therefore, that chemistry assigns, assuming there is value in the calculation at all, a greater activity to these disinfectants than bacteriological experiments will allow. It is possible that chemistry is here indicating a germicidal attainment which is not realised in bacteriological experiments because of the particular physical condition of the fluids (solution). It is well known, at any rate, that the activity of many chemical agents is increased by combining them with certain constituents so that with water the whole forms an emulsion. Advantage of this is taken, for example, in certain industrial bleaching processes in which the article is treated with a mixture of stearine (previously made into an emulsion or saponified) and hydrogen peroxide, sulphurous acid, or other bleaching agent. The bleaching bath is made to contain from 5 to 15 per cent. of the stearine emulsion, together with sufficient of the bleaching agent to effect the removal of colour, and the temperature is kept at about 86° to 104° F. The rapidity of the process apparently depends upon the stearine acting as a carrier and bringing the particles of the reagent into close contact with the colouring matter of the fibres. If our deductions are right there would appear to be some analogy here between bleaching and disinfection, and it will be observed that the bleaching agents, hydrogen peroxide and sulphurous acid. are germicides. The emulsion brings into play the full activity of the bleaching agent, and the same may be true of the germicidal agents (when they are tested under favourable conditions) contained in disinfectants which form emulsions when mixed with water.

There is a suggestion that the bacteriological activity of a chemical agent is better realised in emulsions than in solutions. Hence "Lysol," which is a 50 per cent. clear solution of cresylic acid in soap, or an aqueous solution of carbolic acid, both show a relatively weak germicidal action because in solution the full activity of the agent is not appropriated, and chemical analysis indicates potentialities which fail, how-ever, to exert their full effect on the organisms, because there is not that continual bombardment which is kept up by the Brownian movements of an emulsion. Lord Lister long

THE LANCET, Nov. 13th, 1909, p. 1454.
 THE LANCET, Nov. 20th, 1909, p. 1516.
 In this table Sanitas Fluid was inadvertently classed among tar

ago pointed out, it is interesting to remember, that a solution of carbolic acid in oil had little or no antiseptic power, and his observations were confirmed by Koch. It would thus appear to be an advantage when it is the fact that a disinfectant of the tar class shows, upon dilution with water, a constant state of movement which is not the case when phenol bodies are dissolved in a clear fluid. The emulsions give the full active value of the phenol bodies present; the solution may not, except possibly when it is heated, by which its molecular movement is accelerated. Chemistry may possibly indicate, therefore, what the maximum bacteriological value under ideal conditions can be —a value, however, which is only realised when the phenol bodies travel rapidly through the fluid, as in the case of an emulsion. A low bromine figure under the conditions of experiment indicates, for reasons not yet made clear, high bactericidal potentiality which may be exerted fully when the phenol particles are conveyed rapidly to the organism by myriads of oily travellers. Chemistry suggests the germicidal potentials of a disinfectant, and it is for bacteriology to tell us how far these potentials are realised under varying conditions.

The chemical results suggest the desirability of submitting the various phenolic bodies employed in commercial disinfectants to careful extended chemical examination with the view of unfolding their individual chemical characteristics. So far we have only attempted a differentiation of them by one method which was directed to determining their bromine substitution value. This value certainly appears to have some relation to germicidal value, but a further differentiation is needed which would no doubt give more light upon this point. The fact that varying bromine values are obtained for phenol bodies isolated from different disinfectants proves that we are dealing with different chemical entities each possessing its own germicidal value just as do corrosive sublimate, bleaching powder, peroxide of hydrogen, chinosol, or other definite chemical agents. The fact that certain disinfectant preparations on the market consist of a well-defined chemical substance excluded them from the terms of reference of the present

It would be of interest to know what it is that bromine displaces in phenoloids, whether it is the hydrogen of the hydro-carbon group or of the hydroxyl group, whether possibly the presence or absence of hydroxyl determines possibly the presence or absence of hydroxyl determines germicidal power, or whether and how far the bromine may have oxidised CH₃ groups in such bodies as the cresols. Apparently it is that phenol body which admits least of its hydrogen being displaced by bromine, which is the most powerful germ destroyer. A knowledge of the constitution rather than the composition of the substance would probably supply the explanation of this circumstance, and fresh inquiry will be usefully turned in

this direction.

Another very important question to be decided is the adaptability of the various disinfectant preparations to environment. In practice it is obvious that in a large number of cases the disinfectant has not only disease organisms to deal with but organic complexes also, which are calculated to discount the germicidal power more par-ticularly of the emulsified preparations. We have already referred to some experiments; and we have made a few experiments on the subject ourselves, which showed that organic particles have the power of adsorbing the particles of the emulsion, in consequence of which germicidal value of this class of disinfectant (emulsion) is considerably reduced. Apparently this reduction of germicidal power holds good, not so much for phenol solutions as for emulsions, so that in the presence of indeterminate organic matter (soluble or insoluble) the energetic germicidal action due to an emulsion is sacrificed to a large extent. Organic matter presents an obstruction, so to speak, to the rapid passage to and fro of the agent through the fluid. This fact depreciates the value of the emulsion preparations, and since in most cases they are employed to disinfect, not naked organisms in distilled water, but organisms present in an excess of indeterminate organic matter, it may ultimately be proved by bacteriological experiment that under the conditions of practice emulsions offer no advantages over clear solutions. It must be borne in mind that so far the results of our bacteriological experiments relate only to the testing of the modification we have made use of have we under any

emulsions under conditions presenting no interfering agencies.

If bacteriological analysis, made under conditions approaching those met with in practice, should ultimately prove that the germicidal power of an emulsion is reduced to that of carbolic acid itself, the chemical analysis of the disinfectant will obviously assume further importance. After all, the emulsions have only received the award for high efficiency because they were tested under the non-depreciatory conditions of bacteriological experiment instead of under the depreciatory conditions of practical disinfection. We have also to consider the question of the incompatibility of certain emulsions with salt water, hard water, and so forth. We have made some experiments in these directions, the results of which we hope to report at some future date. Salt and chalk are obviously de-emulsifying agents, and when these are met with in practice they would lead to germicidal deterioration, the value of the disinfectant then simply depending upon the kind and amount of disinfectant substance present, the emulsion having been destroyed.

Some of the disinfectant preparations we found withstood mixing with salt and hard waters better than others. for instance, which are emulsified without the use of soap or resins are compatible with salt or hard water. On the other hand, extreme dilution with hard or salt water of those disinfectants emulsified with soap resulted in the separation of the phenol bodies and neutral oils on stand-To the former the depreciating effect of organic matter still applies; with the latter both organic matter and hard or salt water tend to break up the emulsion, in which case the chances of the germicide coming into intimate contact with the organism are reduced. Here, again, an emulsion would give an exaggerated value in theory but an ordinary value only in practice. The fact that bacteriology under ideal conditions overstates the case from a practical point of view is one of the reasons why chemical analysis has fallen into disrepute. It is held that the emulsions showed increased germicidal efficiency which had no relationship to the amount of germicide present. That appeared to be so when the tests were made under laboratory conditions, but practical considerations indicate that probably in most, if not in all, cases the activity of the emulsion is greatly reduced, as during its service it naturally encounters filth of all kinds. We hope as time and opportunity serve to investigate further these and other important features of the question and to bring the results before our readers at some future date.

PART II. - Bacteriology.

The bacteriological test as applied in our series of experiments has brought out an order of merit for the tar dis-infectants the broad features of which may be accepted unconditionally, though we do not claim for this order absolute accuracy and finality. This order coincides in most cases very closely with that founded on their chemical com-position. When any marked deviation from the parallelism of chemical composition and germicidal power can be demonstrated some difference in physical properties—fineness of emulsion, say -- is usually a marked feature.

In regard to this parallelism it must be borne in mind that the bactericidal and chemical results were arrived at quite independently and in different laboratories, and only when the two sets of figures had been obtained were they brought alongside one another and compared. How remarkable is the coincidence may be seen on reference to Table XXVI. chemical analysis as now carried out affords definite evidence of the presence of a certain proportion of active germicidal substance, certain phenolic compounds, in the tar disinfectants-i.e., it affords evidence that the potent agents are actually present in the disinfectant and in certain proportions; but it cannot do more than suggest how far the germicide present is effective—i.e., how far it is able to do its work under the conditions in which it has to act.

The bacteriological results are so consistent throughout that we have little hesitation in putting them forward as affording an accurate indication of the germicidal power of the disinfectants we have tested. We are fully satisfied on this point, although in our investigation we have not found such high coefficient figures as have been given by other observers. Neither with the Rideal-Walker method nor with than 13. attention to the fact that in our tables the figures obtained check one another most closely, so that the intermediate figures, though not called upon to provide any direct information, are of considerable value in

conditions obtained carbolic acid coefficient figure higher by taking a correspondence between the killing power of In this connexion we wish to draw special carbolic acid and that of the germicide, being tested at any point in a 15 minutes' period where the two happen to coincide in killing the test germ.

Singly, some of the modifications of the Rideal-Walker test appear to be almost trivial, but combined they make building up the general picture of results. We have already possible a much more thorough examination and accurate explained that we have calculated the carbolic acid coefficient determination of the germicidal power of any disinfectant to

TABLE XXVI.—Showing the Comparative Cost of 100 Units of Germicidal Efficiency of Certain Commercial Tar Disinfectants, rechaned from the Carbolio Acid Coefficiency and the Price per Ounce, in Pence.

		Advertised price. in pence, of bottle.	Cost, in pence, per ounce.	Price ratio to carbolic acid taken, at 1s. 4d. per	Germicidal ratio to carbolic	of efficiency

from the data obtained from the two extreme points of our curves, but even a casual examination of the tables will enable anyone accustomed to the examination of such curves to see the importance of the intermediate points as controls. The mean we have used seems to us to be a much more satisfactory figure by which to represent the relative germicidal activity of a disinfectant than the arbitrary figure obtained results.

be tested. For example, without the sterilising apparatus we describe it would be impossible to make the number of dilutions we use unless a very large amount of skilled assistance were constantly available. Without this apparatus, too, it would have been equally difficult to use the larger amount of seeding material which gave us our more regular The platinum spoons used in place of the

needles or öse were the outcome of a large number of experiments made with the object of satisfying ourselves that the quantities taken up in these spoons, although always at least three times as great as those taken up by the ordinary loops, never bear too great a proportion to the 10 cubic centimetres of the McConkey's medium into which the bacilli, after being treated with the disinfectant, are introduced.

How regular these results are will be seen in examining the curves where very few growths appear out of the order in which they might be expected. Were these curves, occurring in the course of a biological experiment, absolutely perfect, not only should we look upon them with suspicion but we should feel that others had a right to do the same. As it is, the intercurrent accidental result acts rather as a control or check on the rest of the figures inserted in the table, this being especially evident where the bacillus coli communis is used, an organism we have employed in preference to all others because (1) the carbolic acid coefficients obtained when this non-pathogenic organism is used as a test correspond very closely with those obtained when the pathogenic bacillus typhosus is employed for the same purpose; and (2) it gives with McConkey's bile-salts glucose broth a definite reaction easily recognised with the naked eye, and no microscopic examination is necessary to determine that we have a growth of the specific organism that was introduced, whilst any accidental contamination with other organisms occurring in the secondary tubes is readily detected, also without any microscopic examination.

At present disinfectants are valued and bought according to their carbolic acid coefficients by Government departments, municipalities, and public and private bodies, and so long as this is the case—i.e., until a better and more reliable standard is obtained—the factor on which price will be based is this carbolic acid coefficient. According to our results, the price per 100 units of germicidal power would work out as in Table XXVI.

It must be distinctly understood, however, that these comparisons as regards the germicidal activity of the various disinfectants can be accepted as reliable only under the conditions of experiment adopted by us, these necessarily being of the simplest and most limited character. Such comparisons must, however, be made and deductions drawn therefrom before any further advances can be made, as germicidal activity must necessarily be taken as the basis of disinfection whatever other factors may ultimately have to be introduced.

As a matter of fact, when we come to deal with the actual process of disinfection it would appear that the physical conditions are on no account to be neglected. So far as we have been able to gain any evidence from the small number of experiments, chemical, bacteriological, and microscopical, on these various disinfectants, it appears that those in solution, as stated above, are most affected by temperature and least by other physical conditions, and that unless they are precipitated from their solutions or locked up by chemical combination with other substances they are the most stable and equable germicides at present at our disposal. Our experience is that with any rise of temperature disinfectants in solution become more potent as germicides. The same holds good of tar emulsion disinfectants, but from the fact that the carbolic acid coefficient falls with a rise of temperature it must be accepted that the rise is not so marked as in the case of the solution. This raises questions of great importance in connexion with the problem of practical disinfection, which, however, must be left for future and fuller consideration and investigation.

In a few preliminary experiments carried out on known bacteria (B.C.C.) introduced into fabrics the disinfectant results have not been of the same order as in the simpler germicidal experiments, the organisms protected by the threads, &c., of fabrics withstanding the action of the emulsified disinfectant much more and for a longer time than that of the disinfectant in solution. We mention these facts merely to indicate that the question of practical disinfection is by no means so simple and activity. This, of course, has been insisted upon by those who have worked at this question, and it may be that ultimately the disinfectants when tested under more practical conditions may have to be arranged in an order very different from that given in our tables, but we believe that, so far as the emulsions, at any rate, are concerned, those which

contain the highest quantity of phenoloids brought into the finest state of division, and having least tendency to combine and remain combined with albumins or with lime or other substances in solution in the materials to be disinfected, will be found to be the most efficient.

It is unfortunate that in all bactericidal tests as at present performed the figures obtained convey no real idea of the disinfecting work under natural conditions of which the substance is capable; these figures give merely a comparison, bounded by narrow conditions, between the germicidal power of phenol and that of the disinfectant under consideration, whilst we know practically nothing of what this germicidal power of phenol really is when applied to disinfection under these natural conditions. To deal with practical problems it seems clear that this latter question must be first decided, and this will mean extensive investigations on the modifying factors involved in practical disinfection. When we are able to say that the temperature at which disinfection is to be carried out will modify the necessary strength of the dilution by multiplying or dividing by a given figure for each degree above or below that taken as the standard; when we are able to refer to similar figures to modify our coefficient, representing each type of organism to be destroyed, the type of surrounding conditions in which it is found, the type of material to be disinfected and its surface, soft, hard, irregular, or spongy, that soak up fluids or repel them and the like; when we are able to modify the figures according to the physical and chemical nature—emulsion or solution of the diluted disinfectant, to allow for the influence of the diluting fluid—hard or sea water or water containing organic matter; when such points as these are cleared up and tables of figures obtained to which reference may be made and the coefficient figure modified in accordance with the required conditions, then and then only will it be possible to use such narrow standard tests as those we at present utilise as a definite foundation on which to base the solution of the problems of practical disinfection.

The two sets of data that will be required are:—Firstly, a figure representing the dilution of the disinfectant which will sterilise a standard amount of a culture containing a standard number per cubic centimetre of a standard organism in a standard time. Secondly, reference tables giving a series of figures which can be used to multiply or divide the figure representing the strength of the dilution found above, so that it may be brought into line with the conditions under which it will have to perform its work. With such a series of factors and their influence before them the makers of disinfectants would be able to state definitely in their printed instructions what strength should be used for each purpose and to suggest what modifications would be necessary under any given set of conditions.

We believe that it is along these lines that future research should be pursued, and that until these details are forth-coming it is, and will be, impossible to determine what dilutions may be used, safely and economically, to attain effective disinfection under the varying and varied conditions met with in practice.

CONCLUSIONS (CHEMICAL).

A.—The evidence as regards a physico-chemical standard suggests, in the case of, at any rate, most of the tar disinfectants used for general purposes—that (1) the disinfectant should contain a reasonable amount of active bodies, e.g., phenols or phenoloids, and (2) that the dilutions with water should exhibit Brownian movement, in other words, should form a satisfactory emulsion.

B.—There is no objection to disinfectants of varying qualities being sold to the public, but it is desirable that price should be commensurate with quality, which, as will be seen from Table I., is not always the case. There can be no praise awarded to a phenolic or tar disinfectant which, when tested bacteriologically under what may be termed ideal conditions, shows an indicated germicidal value less than that of carbolic acid itself. In chemical terms $\frac{P-B}{3}$ should be over

unity, and that condition should be associated with the fact that the disinfectant produces a satisfactory emulsion with water. A consideration of the results of analysis of a number of disinfectants commonly supplied to the public and of the prices charged for them shows that

manufacturers can supply, presumably at a reasonable profit to themselves, 100 units of phenolic body at a retail price varying from sixpence to a shilling having a carbolic coefficient varying from 5 to 9.

As we have shown, the value $\frac{P-B}{3}$ can be rapidly determined by chemical analysis, the estimation of soaps, resins, and neutral oils being of little consequence. Ocrtainly the method quickly brings to light the ineffective article, and distinguishes further the feeble from the strong.

C.—We put this formula forward as a possible useful guide to the differentiation of tar disinfectants, but further work is needed on the subject before we can make quite certain of the validity of the proposal. There is here, at any rate, a set of experimental results which distinctly suggests that chemical and germicidal action under the most favourable conditions are analogous, and the bromine-combining value of a phenoloid appears to give a clue as to the power of that body to kill organisms.

CONCLUSIONS (BACTERIOLOGICAL).

A.—The Rideal-Walker method of testing disinfectants certainly gives accurate information under well-defined and strictly limited conditions, but results that can be set down in definite black-and-white figures are exceedingly difficult to obtain.

B.—The modifications of this method utilised in our work, while rendering the test less liable to aberrant results, ensure a clearer and more expanded picture of the germicidal power of a disinfectant than has hitherto been obtained.

C.—There can be no doubt that the coefficients as given in Table XXIV. indicate that the various disinfectants sold to the public have very different germicidal values; this doubtless is associated with the proportion of the germicidal chemical agent present and the physical conditions under which it exists.

D.—It is obvious that measured by such a standard certain of the disinfectants now on the market must have a relatively small, and in some cases very small, germicidal value.

E.—Never in our investigations having found such high carbolic acid coefficient figures as have been given by other observers to certain disinfectants, we are of opinion that many have had claimed for them an exaggerated value, when compared with carbolic acid, which is by no means justified.

F.—Results obtained in such bacteriological experiments as those we have carried out, although giving a germicidal value to a disinfectant acting under the most favourable conditions, afford little indication of their germicidal value when used in practical disinfection.

G.—It is evident, then, that much remains to be done in the solution of such problems, amongst others, as arise in connexion with (1) the presence of foreign substances in the material to be disinfected; (2) the temperature at which the disinfecting process is carried on; (3) the fluid with which the disinfectant is diluted—hard water, soft water, sea water, &c.; (4) the type of micro-organism that has to be destroyed in the process of disinfection; (5) the nature of the substance and the character of the surface of the material to be disinfected; and (6) the duration of the disinfecting process.

H.—Only when the influence of such factors as the above have been determined will it be possible to modify any standard coefficient figure, and thus obtain data for the preparation of effective and economical dilutions to be used in meeting the various problems of disinfection.

SIDLAW SANATORIUM.—A meeting of the donors and subscribers to the Sidlaw Sanatorium was held in the Burgh Court Room, Dundee, on Nov. 17th. The town clerk intimated the resignation of eight directors. Professor D. MacEwan proposed that the retiring directors should be asked to postpone their resignations until the matter had been gone into, and that a committee consisting of the directors and subscribers should be appointed to report fully on the whole matter. Notwithstanding the present position of affairs and that the deficit was equal to £40 a month, provided that some attempt was made to get additional subscribers, he thought that it would be possible to continue the institution. He suggested that a conference might be held with the directors of the Royal Infirmary re the question of receiving tuberculous surgical cases of children into the sanatorium. It was ultimately agreed to call a public meeting

SOME CONSIDERATIONS OF MEDICAL EDUCATION.

V.1

The Reform of the Curriculum.—Instruction without Examination.—Various Schemes for Arrangement of the Curriculum. —The Educational History of 1111 Qualified Men.

In May, 1905, an important debate again ensued in the course of the proceedings of the General Medical Council upon the question of the possibility of including certain subjects in the medical curriculum without requiring examinations on them, the debate arising out of the report of the Education Committee of the Council upon the subject. The Education Committee reported that it had endeavoured without much success to obtain the information which had been requested on the whole matter by the Council; that certainly there were subjects, such as vaccination, ophthalmology, mental diseases, and infectious diseases, which formed part of the compulsory curriculum, but in which no special examinations were held, although pupils knew that questions might be asked upon them; and that there was no country in Europe where the certificate of a professor or teacher is taken by a faculty of medicine in lieu of examination.

Dr. Mackay desired to remit to the Education Committee, later amended to a committee of the Council, to prepare and present a detailed report upon the system of examination in medicine followed in other countries, with the special object of determining the number of professional examinations demanded, the subjects included in these examinations, and the value, if any, attached to the records of class attendance and work. The Council, however, rejected the motion, and the ingenious method of rearranging the curriculum by omitting from the test of examination subjects in which the students might be considered to be hall-marked by their teachers was thus shut down upon. Undoubtedly such a scheme has many risks, but Dr. Mackay's proposal might have been found not to differ very much from methods in practice if any committee of the Council had had time and opportunities to make the wide investigation which he advocated. But such an investigation would have had to be very thorough before its results would have justified the Council in a dashing departure.

The late Dr. Lindsay Steven, one of the best and most practical authorities on medical education in the General Medical Council, and one whose death was much deplored by his colleagues, proposed a motion:—

That it be remitted to the Education Committee to consider and report to the next session of Council whether the adoption by the Council of one or other or both of the following resolutions would not help to secure the attainment of the object the Council had in view in instituting the five years curriculum, viz.: (1) That the preliminary scientific examination in physics, blology, and chemistry should be passed before the student begins the qualifying study of anatomy and physiology; (2) that before being admitted to the final examination the student should produce evidence that he has devoted the last year of his curriculum exclusively to practical and clinical work and study.

The Education Committee of the Council had these questions under consideration for some time and finally reported that the operation of the first resolution might have the effect of causing an undue amount of time to be devoted to the preliminary sciences, with two possible subsequent results. "Either the student," the report ran, "will be tempted to crowd the rest of his study into the remaining two or three years, as the case may be, of the five years' curriculum, a course to be seriously deprecated, or he will be compelled to take one or more additional years. The committee is of opinion that the main effect of the proposed change would

receiving tuberculous surgical cases of children into the sanatorium. It was ultimately agreed to call a public meeting on an early date.

1 Nos. I., II., III., and IV. were published in The Lancet of Oct. 23rd (p. 1232) and 30th (p. 1301), and Nov. 13th (p. 1459) and 20th (p. 1531), 1909, respectively.

be to seriously lengthen the curriculum and thus to render entrance to the profession more difficult and expensive than it now is." As things now are the curriculum is far more often one of six or even more years—and this even in the case of industrious students-than one of five. The committee noted that the proposal did not contemplate the transference of the subjects it deals with to the preliminary course of study, which would withdraw from the Council the direct supervision of the arrangements for teaching them, nor did it seek to enact any special provision, the natural sequence of such a transference, for determining the length of the curriculum subsequent to the completion of the examination in chemistry, physics, and biology.

With regard to the second resolution, the committee considered that distinct evidence of clinical and practical study in the fifth year should be produced by the student, showing that his time in that period of his curriculum had been mainly occupied in such work, but it would not suggest any regulation which should absolutely limit the work of each session of the period of professional study. reminded the Council that the present recommendation is to the effect that regulations should be so framed that attendance on systematic courses may be concluded at the end of the fourth year of study, and while agreeing with this, the Education Committee would not advise that any proposal should be sanctioned which would prevent a student from supplementing his clinical study by suitable systematic work. The committee held that this resolution also would tend to lengthen the medical curriculum.

The debate which followed on this report showed that the Council felt the danger of thus attempting to divide the medical curriculum into watertight compartments, and every teacher or examiner of experience must agree with this view. On the whole it is better that the student should finish with his preliminary scientific subjects before tackling the professional studies of anatomy or physiology. Similarly, on the whole it is better that the last year of the student's course should be occupied in clinical work, familiarity with which is after all the object of his education. But it would be wrong to make such an arrangement of the student's time compulsory upon him. There are students of different circumstances, students of different equipment, and students of different powers of learning, and some amount of elasticity must be permitted in the curriculum to meet such varying requirements.

But the debate on Dr. Lindsay Steven's double-barrelled motion led immediately to an interesting motion by Sir Henry Morris in the following terms :-

That it be referred to the Education Committee to consider and report to the Council (1) as to the desirability of transferring the preliminary science subjects—physics, biology, and chemistry—from the curriculum of medical studies to a stage preliminary to the commencement of the curriculum; (2) as to the advisability of requiring a five years' period of study even after removing from the curriculum these preliminary scientific subjects.

This motion was a bold recognition of the fact that the majority of medical students do not obtain their qualifications after five years only of study, but that, on the contrary, the curriculum is really one of six, or more than six, years. Sir Henry Morris advocated his motion in a strong speech based upon personal knowledge, in which he deplored the demands made upon the time of the medical student by purely scientific teachers. But the report of the Education Committee, upon a remit, was unfavourable to the first suggestion and postponed consideration of the second. It was clear, as the committee pointed out, that the proposal to transfer the study of physics, biology, and chemistry to a stage preliminary to the commencement of medical education proper (i.e., of the medical curriculum) involved important questions as to the standard at present reached in the secondary schools of the country; while the whom 542 qualified in England, 402 in Scotland, and 167 in

committee might have added that in such a country as Ireland where no facilities exist at secondary schools for the teaching of elementary science, the innovation would have borne very hardly. A special committee of the Council had drawn up in 1904 new syllabuses for the guidance of examining bodies in the subjects-of chemistry, physics, and biology, and considered that the effect of these syllabuses upon the educational course in its present shape ought to be given due trial.

We must make further reference to the subject of science teaching in secondary schools, for Sir Henry Morris here introduced a subject of the very greatest importance to many of the best educational institutions in the country, and it is certain that the attitude and opinion of the science masters in the public schools will have to be taken into consideration by the Council. For the time, however, his scheme for the readjustment of medical studies failed to find favour with his colleagues. But the reiteration of plans for the arrangement of the medical curriculum marked the sense of the Council that the present state of affairs was unsatisfactory, and at the next session Sir John Batty Tuke came forward with a plan for a new grouping of the medical curriculum. He asked the General Medical Council to make it a requirement in regard to professional education that all the subjects should be divided into two main groups, one comprehending physics, chemistry, elementary biology, anatomy, and physiology, and the other comprehending all the other subjects; and further, that no licensing body should recognise instruction in any subject comprehended in the second group until candidates have passed in the subjects comprehended in the first group. An interesting debate followed. Sir John Batty Tuke supported his suggestion that a block of this sort should be introduced into the student's curriculum by alluding to the more elaborate nature of the education of the medical student and the increasing stringency of his examinations. The late Sir T. McCall Anderson, though in sympathy with Sir John Batty Tuke as far as the proposal was designed to prevent neglect of the final subjects owing to the pressure of the intermediate subjects, thought that such a scheme left the door open to an extension of the time of the curriculum to which he was entirely opposed. He therefore moved as an amendment that a minimum of two years should be devoted to the subjects of the final examinations, and that no qualifying courses on these subjects should be recognised until all the previous examinations were passed. Sir Henry Morris again advocated taking the preliminary scientific subjects out of the curriculum, and it was decided to remit these various proposals.

But yet another plan was brought forward, Sir John Williams proposing a slightly different scheme in which the subjects for the medical curriculum were to be divided into three groups corresponding with the usual divisionsnamely, (1) the preliminary scientific subjects, (2) the intermediate subjects, and (3) the final subjects; but it was to be made compulsory that any instruction in any subject of the last two groups should not be recognised until the candidate had passed in the subjects of the previous group. This proposal again implied definitely dealing with medical education in watertight compartments and was duly remitted to the Education Committee. By this time the Education Committee had its hands very full, but at the summer meeting of the Council in 1907 an interim report was presented to the Council by the committee which deals incidentally with many of the suggestions which had been remitted to it.

The report contained the educational history of 1111 licentiates and graduates in medicine in the year 1906, of

It was found that of these 80 per cent. had commenced their study at an age falling within the period of five years from 17 to 21, 5 per cent. having entered when younger than 17 and 15 per cent. when older than 21. The age at which these students qualified was also capable of being divided into three groups, having a certain similarity that is to say, 80 per cent. of the 1111 students qualified within the seven years period between 23 and 29 years of age, while 5 per cent. qualified younger than 23, and 15 per cent. qualified older than 29. The Education Committee asked for permission to obtain further information with regard to the dates of the professional examination of these 1111 gentlemen, a proposal which was unanimously agreed to. In this way it would be possible to see at what points in the curriculum particular difficulty seemed to be experienced by the student, as well as to gauge how far time overspent in one direction was apt to lead to scamping in other parts of the curriculum. This interim report also contained the interesting fact that in 1906 the mean length of the curriculum of those who qualified was 6 years 11 months—namely, 7 years 4 months in England, 6 years 6 months in Scotland, and 6 years 5 months in Ireland. This interim report was a most valuable document. The number of students dealt with was large enough to make deductions from the figures fairly applicable to medical students as a whole, whether English, Scottish, or Irish: while the ascertainment of the average age of entering upon study and the average period devoted to study gave tangible ground upon which to build any schemes of reform.

A report of the Education Committee on the curriculum in medicine was submitted to the Council at the winter meeting of 1908, for which excellent piece of work (see THE LANCET, Dec. 5th, 1908, p. 1683 et seq.) the Council was mainly indebted to Principal Mackay. The report is of too recent date to need any summarising. It showed that a certain extent of overlapping inevitably took place in the student's career, and that the time in the curriculum which should be devoted to the final subjects was encroached upon; and it proposed the division of the course into two reasonable limiting periods. The consideration of the report, after an interesting debate, was postponed until the following session, that of May, 1909, and was then further postponed until the session now in being, where the whole matter is under discussion (see THE LANCET, Nov. 27th, p. 1641.

(To be continued.)

COMPLIMENTARY DINNER TO PROFESSOR ARTHUR ROBINSON.—The Medical Faculty and Senate of the University of Birmingham, together with a few private friends, entertained Professor Arthur Robinson, recently professor of anatomy in the University to dinner on Nov. 20th, in the University Club, Birmingham, on the occasion of his leaving the city to take up his new duties as pro-fessor of anatomy in the University of Edinburgh. The principal of the University, Sir Oliver Lodge, presided over the company, which numbered 45, among whom were Professor G. Barling, Professor J. H. Poynting, and Professor Hughes, deans of the Faculties of Medicine, Science, and Arts respectively, many of the professors, and some prominent public men. Sir Oliver Lodge proposed the toast of "Our Guest" in the happiest of terms. He spoke of his skill as a teacher, his renown as an anatomist, and his sterling qualities as a man. Professor Barling also spoke, and referred to the able assistance Professor Robinson had given him as sub-dean during the five years of his tenure of office in the University. He eulogised his services to the school as a teacher, investigator, and administrator. Professor Robinson made a feeling and appropriate reply, speaking particularly of the progress which the Birmingham Medical School had already made and of the promise it held out of still greater progress in the future. A most enjoyable evening was spent and a right hearty send off given to Professor Robinson.

THE REPORT OF THE INTERNATIONAL OPIUM COMMISSION.

THE International Opium Commission, which was called together on the initiation of the United States Government, met at Shanghai on Feb. 1st of this year. Thirteen Governments were represented, and their deliberations were opened by an address of welcome in Chinese from the Viceroy of Liankiang, who had been nominated for this purpose by Imperial Rescript, the address being afterwards repeated in English by a member of the Viceroy's staff. The report of the Commission is now issued in two parts. The first, extending to 118 pages of folio, contains the official minutes of the proceedings and the resolutions ultimately adopted, the latter being printed both in English and in French. The second part, with nearly 400 pages of folio, gives the complete reports and memoranda on the subject matter of the Commission as presented by the countries represented. These relate to the area and location of poppy cultivation, the manufacture and distribution of opium, the restrictions governing its importation and exportation in the countries affected; they relate also to the pharmacy and other laws regulating the sale of morphia and other derivatives and compounds of opium.

The following are the Governments which were represented: The United States of America (3 delegates), Austria-Hungary (1), China (4), France (3), Germany (2), Great Britain (5, including 1 representing Canada). Italy (1), Japan (3). the Netherlands (2), Persia (2), Portugal (2), Russia (1), and Siam (3). The British delegates were the Right Hon. Sir Cecil Clementi Smith, G.C.M.G., who has had considerable administrative experience in the Far East; Sir Alexander Hosie, H.B.M. Consul General; Mr. William Lyon Mackenzie, C.M.G.; Mr. James Bennett Brunyate. acting Financial Secretary to the Government of India; and Mr. Robert Laidlaw, M.P. The British delegates were assisted by two assessors—namely, Mr. Warren D. Barnes, Secretary for Chinese Affairs, Straits Settlements and Federated Malay States; and Mr. Cecil Clementi. Federated Malay States; and Mr. Cecil Clementi, Assistant Colonial Secretary, Hong-Kong. Of the total 32 delegates only four were medical men-viz., Dr. Hamilton Wright, one of the American representatives, who we believe was formerly engaged as director to the Medical Research Institute at Kuala Lumpur, Federated Malay States; Dr. Y. Tahara, director of the Imperial Hygienic Laboratory, Tokio; Dr. T. Takaki, director of the Medical School and Chief of the Sanitary Bureau of the Government of Formosa; and Dr. Hsü-Hua-Ching, President of the Army Medical College and Expectant Taotai of Chihli. The delegations which took the largest share in the proceedings of the Commission were the American, the Chinese, the British, and the Japanese; but the two nations chiefly concerned in the proceedings were the Chinese and the British. As the opium question, in our opinion, is very largely a medical one, it is to be regretted that Britain did not adopt the same course as America, Japan, and China, and appoint at least one medical expert among its representatives. At the opening meeting, at the close of the Viceroy's address, the chief French delegate made a direct application to him that the official language of the Commission should be French, but the Viceroy entirely ignored the request and left the meeting without giving an answer. Ultimately it was decided to

The Commission chose as its chairman the chief American delegate, the Right Rev. Charles H. Brent, D.D., Bishop of the Philippines, who, it may be mentioned, acquitted himself admirably in the difficult position which he was called upon to hold. It appears that for some considerable period negotiations had been in progress for the establishment of an International Commission on the Opium Question. At first it was proposed to restrict the nations invited to participate in the Commission to those which, through territorial possessions, commerce, &c., were actively interested in the opium question in the Far East. Later, however, the scope was considerably widened, and finally delegates were summoned from the 13 Powers already named. The Commission was intended to be one of inquiry, with a view to collect information and exchange views between the various Governments concerned, with the hope that this might lead later to

make English the official language of the proceedings.

¹ Report of the International Opium Commission, Two vols, London: P. S. King and Son. 1909. About 500 pages. Price 10s. net.

the holding of an International Conference on the Opium Question. The chairman of the Commission at the beginning of the deliberations expressed the hope that the resolutions passed would be unanimous; that the recommendations would be of a practical, broad, and wise character; and that before coming to any decision the whole question would be studied from all its aspects—moral, economical, commercial, and diplomatic. We learn with some regret that the views of this broad-minded cleric upon the attitude to be adopted in examining this difficult question have not given satisfaction to a section of the more irreconcilable anti-opium enthusiasts in his own country and elsewhere. Before proceeding to propose and pass resolutions the various delegations put forward a brief statement of the opium question as it related to their own country or its dependencies. From what the chief Chinese delegates said it appeared that the national conscience of China has been recently awakened, and that there was a general movement on foot to rid the country, if possible. of the degrading opium habit. He made an impassioned appeal to the other nations to give their help in suppressing the abuse of opium in his country. Owing to the imperfect manner in which statistics are compiled in China it was not possible for him to give precise figures as to the number of persons who were addicted to the abuse of opium in the Chinese Empire, but it was safe to say that more than 25 per cent. of the adult population used opium habitually in excess. It was also impossible to state the amount of opium grown in China or the amount imported from India or elsewhere into the Empire, as much of it was smuggled into the country. A change was coming over the subject by the substitution of morphia, taken by the mouth or injected hypodermically, for opium smoking. Enormous quantities of morphia were now being imported clandestinely into China, the comparative cheapness of this drug (1 dollar's worth going as far as 3 dollars' worth of opium), the facility with which it can be obtained, and the ease with which it can be administered, all making it clear to the coolie that economy and convenience were attained by its use in place of opium. Morphia of Japanese origin could be sold cheaply, and consequently it had a virtual monopoly in Manchuria, the Yangtse valley, and other populous parts of China. A peculiar and recent phase of the opium question, especially in China, is the fact that nowadays, perhaps in response to the growth of public opinion against the opium habit, a large number of so called anti-opium remedies, chiefly in the form of pills, are in the market, and are sold to the public in large quantities. Unfortunately, these remedies for the most part contain morphia or opium in one form or another, and this been proved by analysis, so that the result is the substitution of oplum eating for oplum smoking. Although the oplum smoking divans have in many places been closed this cannot be regarded as evidence of diminution in the amount of misuse of the drug, for the victim of the habit can now drug himself at home without resorting to a divan at all. Another remedy named "Peking tea" is merely black tea impregnated with morphia. Although to some perhaps these so-called antiopium remedies may be taken in good faith with a view of casting off the yoke of the opium habit, nevertheless it is well known throughout China that these remedies are only substitutes for the opium pipe. Unfortunately, the demand for them is so great that many drug stores, native and foreign, are doing a lucrative business in making and selling these specifics. While the laws of China appear to be unable to deal satisfactorily with these "medicines" containing morphia, the selling of that alkaloid for illegitimate purposes is punished, when detected, by the penalty of The chief Chinese delegate went so far as to decapitation. assert that in Shanghai, where the commission was sitting, British, French, Austrian, and Japanese druggists, as well as others, were selling anti-opium pills which on analysis had been shown to contain morphia or opium. One particular pill of this sort manufactured by a Japanese firm commands the largest sale in China, and is carried to all the corners of that empire owing to the enterprise of its proprietors.

The evils, moral and physical, produced by the opium habit are universally admitted, and the Chinese delegation spoke in strong terms as to this. He said that Western China especially had been ravaged by this accursed habit. "Visit," said he, "the dismal and wretched hovels which

were it not for this opium would be happy homes; see the emaciated, depraved multitude of victims to this vice observe the abject poverty, and notice for the cause of it all the wide fields once covered with the waving gold of ripening grain now given over to the culture of the poppy. concluded his speech with a fervent request to his fellow delegates for help from their Governments towards crushing the opium curse in China. He asserted that the Chinese nation had at last awakened to its evils, and the sentiments of the people had been stirred as they had never been stirred before during 2000 odd years of history. All classes were united in the determination to get rid of the curse. China looked for the fullest assistance and cooperation of all civilised powers in her attempt to "throttle the opium evil." He hoped in conclusion that such restrictions of the existing treaties as might be found to hamper her efforts in dealing with this question would not be used to this end. The British chief delegate then pointed out that the task of prohibition of opium in India was impracticable in the near future, and he added that the British delegation was unable to accept the view that opium should be confined simply and solely to medical uses. He objected to the Chinese delegate's suggestion that England should abrogate its treaties with China on the opium question, but he affirmed that the British Government would strictly adhere to its agreement so recently made as in 1908 to restrict for the next ten years the importation of opium from India by 5100 chests annually into China until a fixed minimum of 16,000 chests a year was reached, notwithstanding that this arrangement would entail a heavy loss of revenue to the Government of India. The Japanese view was that the best and most practical way of dealing with the opium habit was by gradual abolition, so that men and women addicted to the vice might break off the habit with least inconvenience to themselves.

Ultimately, after the proceedings had lasted over 14 sessions, from Feb. 1st to Feb. 26th, and as a result of considerable discussion, the Commission passed a series of resolutions, having for their object the suppression of the morphia habit and the gradual eradication of opium-smoking. Other recommendations related to the correcting of the abuse of opium and its derivatives in foreign concessions and settlements in China, that there should be a revision of the existing system of regulations in countries where opium is not prohibited for other than medical purposes, and that each delegation should advise its own Government to investigate scientifically for itself the matter of anti-opium remedies and the effect of opium and its products. Finally, international coöperation was advocated to prevent the smuggling of opium into countries where a prohibitory law prevails.

The report is of special interest in view of the statement made by Sir Edward Grey in the House of Commons on Nov. 4th to the effect that the British Government was considering a proposal made to it by the Government of the United States that an International Conference on the Opium Trade should be held shortly at the Hague.

MEETING OF METROPOLITAN PRACTI-TIONERS AND THE DIRECT REPRE-SENTATIVES ON THE GENERAL MEDICAL COUNCIL.

DR. J. FORD ANDERSON presided at a meeting of the members of the medical profession who reside in London and its neighbourhood which was held under the auspices of the Metropolitan Counties Branch of the British Medical Association at the St. James's Vestry Hall, Piccadilly, W., on the evening of Nov. 22nd.

Dr. H. W. Langley Browne, who spoke first, after briefly sketching the history of the General Medical Council, whose position, duties, and possibilities, he said, were not fully understood either inside or outside the profession, proceeded to refer to an inconvenience in the arrangement of the medical constituency for election purposes. Each representative, he thought, should represent a division of the country and not the whole. At the time of the last election for Direct Representatives, although the clearest regulations were sent out, 1503 of the returned papers were invalid because they were inaccurately filled up. Out of a total number of 24,659 only 11,000 odd

were returned in the proper time and 11,000 odd were not returned at all. This had a bad effect, because it fostered the idea that medical men were apathetic with regard to their interests. The speaker then referred to the committee which the Council had appointed to inquire into unqualified practice in this and other countries. Lord Crewe, the Foreign Office, and the Colonial Office had rendered great help in this inquiry, with the result that a large amount of information had been obtained and a digest had been made which could be obtained at the offices of the Council. This inquiry showed that in almost every country except our own unqualified practice was not allowed to exist or was greatly restricted. He did not think there would now be much difficulty in getting the unsatisfactory Clause 40 of the Medical Act altered. The Local Government Board had sent out circulars to medical officers of health asking for information with regard to unqualified practice in their districts, but he thought that the general practitioners had better means of knowing the condition of things in their respective areas than medical officers of health, and he believed that in some cases the inquiry forms had been returned without investigation having been made.

Dr. H. A. LATIMER said that the limitations of the Council were not rightly understood, and he gave several amusing instances of irrelevant questions which were put to him when standing before his election by some of his constituents. The Act of 1858 was faulty and failed to protect the medical profession as it should do. Referring to the unsatisfactory nature of Clause 40 he said he knew of cases where masseurs and bonesetters had given evidence in courts of law as to injuries. The colonies were far ahead of this country in regard to the protection of the public and the profession, and the new colonial enactments of Bermuda, Newfoundland, and British Central Africa went further than any legislation in this country. Of late our legislators were becoming more careful of the health of the country. A Midwives Act had been passed which had been rather detrimental to the medical profession, but which in the end he believed would be beneficial for all parties. That was a great step in the right direction, but if the health of the country was to be properly safeguarded no unqualified person whatever should be allowed to practise. Although the Council had not been able to do much with regard to individual quackery, it had done something towards preventing what he called corporate quackery, for the charters of opticians and medical herbalists had been successfully opposed. A part of the lay press were responsible for the sale of many quack remedies, and it was significant that some newspapers had refused to advertise the publication relating to proprietary remedies which had lately been issued by the British Medical Association. The Council as a body kept a very jealous eye upon medical education. The penal work of the Council, under the able guidance of its distinguished presidents, of whom Sir Donald MacAlister was not the least, had been so carefully done that attempts to upset it had almost invariably failed in the courts. He thought that the Direct Representatives had been successful in doing the work they were required to do, and an additional representative had been granted. With regard to the method of electing Direct Representatives, he was strongly in favour of creating con-

Dr. L. S. McManus, after paying a tribute to the able leadership of Dr. Langley Browne, said that the constitution of the Council was radically wrong, and was likely to remain so unless pressure were brought to bear from outside. The representatives of the corporations were not in touch with those whom they were supposed to represent. He briefly sketched the way in which penal cases were dealt with, remarking that, contrary to the general idea, the Council always leaned to the side of leniency. Referring to the method of electing representatives he said that England should be divided into three districts, north, middle, and south, and Wales should have the fourth representative. There should be legislation which would allow the Council to deal with quacks of all sorts. The watchword of the profession should be cooperation and organisation, things which it had lacked in the past. The medical profession ought to be represented in Parliament by medical men. If such had been the case would any Cabinet Minister have dared to put that objectionable clause in an Act requiring medical men to be fined if they failed to notify a birth within 36 hours?

Dr. MAJOR GREENWOOD asked for some expression of

opinion from the Direct Representatives on the Poor-law Commission report.

Dr. LANGLEY BROWNE said that his sympathies were to a large extent with the Minority Report, but that he was not prepared at the present moment to make a statement with regard to the matter.

A very brief discussion took place with regard to prescribing chemists, Dr. G. A. HERON remarking that he had interviewed many of the leading chemists who had told him that they were quite willing not to prescribe if medical men would undertake not to dispense.

The CHAIRMAN, reading a question that had been handed up to him, asked Dr. Latimer whether there was an early prospect of suppressing the sale of patent drugs.

Dr. LATIMER thought that at present it was impossible, but that much might be done by requiring their exact composition to be stated on the label. The public would then be careful not to pay 1s. $1 \pm d$. for a box of pills which cost $\frac{1}{4}d$.

The proceedings terminated with a vote of thanks on Sir Victor Horsley's proposal, to the three representatives for their attendance at the meeting.

ASYLUM REPORTS.

City of Cardiff Mental Hospital (Report for the Year 1908).—The total number of cases under treatment during the year was 764, this being also, as the hospital is a new one, the number of admissions. The discharges amounted to 49, and of these 28 were recovered. The deaths numbered 31, and necropsies were held in 30 cases. Upon Dr. Edwin Goodall has fallen the brunt of the work in the preparation of this hospital for the reception of mental patients, and the careful planning and organisation which have been devoted to it are characteristic of modern methods utilised and developed by a physician who has appreciated their enormous value. We cannot do better than quote from Dr. Goodall's report. "The institution is equipped much above the average in respect of scientific apparatus for clinical and pathological research. Such equipment is necessary in every hospital for mental diseases if the medical spirit, without which these institutions would rank merely as places of detention, is to be fostered, and young medical men of a desirable stamp are to be attracted. More than ever is it incumbent to have such in a mental hospital in touch with a town possessing medical laboratories and trained workers in all departments of medicine, which provides post-graduate instruction, and which aims at possessing a complete medical school." When we read of this or that asylum having a remarkably low rate of maintenance, we are not, therefore, to envy that institution forthwith, and to set it up as a model to be followed. Before congratulating the authorities we require to be satisfied upon a few points. What, in brief, are their ideals? Is the institution merely a home of rest, where the "patients" are clothed, fed, and amused, where the medical service wholly or mainly consists in a perfunctory round, and attention to the "primæ viæ"; where employees, to whom courtesy accords the designation of "nurse," patrol the wards in the proportion of 1 to 10 or 12 patients? How many of the patients drift into dementia because they have not, for reasons of want of confidence, been sent in early enough, and because they have received no treatment worthy the name, in order that expenses may be kept down? Dr. Goodall is of opinion that if people appreciated that an extra 4d. per head per week or so meant to their relatives a better chance, better medical attention, more refined and skilled nursing, constant effort to prevent dementia and promote more rapid recovery, a putting off of the evil day of extensions to buildings, they would consider the extra expenditure not only justifiable but desirable and in the long run a real economy. Nothing could be better than that these objects should be the aim of every authority in lunacy in the country.

Suffolk District Asylum (Report for the Year 1908).—At this asylum the total number of cases under treatment during the year was 1100. There were 230 admissions. The discharges numbered 166, and of these there were 42 recovered. The recovery rate, calculated upon the net admissions, was 22.4 per cent. The death-rate, calculated on the average

number resident, was 12 per cent. Dr. J. R. Whitwell, who issues the report, states that of the total number of deaths 20 per cent. were due to some form of tuberculous disease.

THE JOHN HERBERT WELLS FUND.

THE following is the third list of subscriptions promised to or received by this fund, which is in aid of the widow and children of the late Dr. John Herbert Wells who died recently from the effects of an accidental infection contracted whilst preparing a vaccine from the glanders bacillus, with which he succeeded in curing his patient. (THE LANCET, Oct. 23rd, p. 1253.) Further subscriptions will be gratefully received by the Earl of Dalhousie and Mr. Julian G. Lousada, the honorary secretaries and treasurers of the fund, at 16, Old Broad-street, E.C., or by ourselves at this office:—

UNIVERSITY COLLEGE, LONDON.—The new botanical laboratories at University College (University of London) will be opened on Friday, Dec. 17th, by Dr. D. H. Soott, F.R.S. The Vice-Chancellor (Professor M. J. M. Hill) will preside. Applications for tickets of admission should be made to the Secretary, University College, London, W.C.

THE

MEDICAL PROFESSION AND MUNICIPAL HONOURS.

THE following members of the medical profession have been elected or re-elected to the mayoral chair. Brief notes of their medical and municipal careers are given:—

Aldeburgh.—Mrs. Elizabeth Garrett Anderson, M.D. Paris, L.S.A., who last year was honoured by being the first lady mayor to be elected under the Act of 1907, which admitted women to town councils, has been re-elected Mayor of Aldeburgh. She obtained the diploma of L.S.A. in 1865, and graduated in the University of Paris in 1870. In 1866 she became senior physician to the New Hospital for Women, and subsequently consulting physician. She was also dean and lecturer on medicine at the London School of Medicine for Women and visiting physician to the East London Children's Hospital.

Lymington.—Mr. Edward F. Chinery, F.R.C.S. Edin., M.R.C.S. Eng., L.S.A., the Mayor of Lymington, received his professional education in Edinburgh and London. He became a Fellow of the Royal College of Surgeons of Edinburgh in 1880. He practised at Lymington for 38 years, retiring in 1906, and has since spent his well-earned leisure in visiting various parts of the world. He is an ex-chairman of the Southampton branch of the British Medical Association and has been a justice of the peace for Lymington for some years.

Montgomery.—Mr. Nicholas Watson Fairles-Humphreys, M.R.C.S. Eng., L.S.A., who has been re-elected Mayor of Montgomery, was born in 1837 and studied medicine at St. Bartholomew's Hospital. In 1885 he was elected alderman for the borough of Montgomery and has been 11 times mayor. He is a justice of the peace for the county of Montgomery, was high sheriff in 1882-83, and has been a county alderman since 1889. His grandfather, Nicholas Fairles, justice of the peace for the county of Durham, was the originator of the lifeboat movement and chairman of the first committee.

Newark.—Mr. F. H. Appleby, M.R.C.S. Eng., L.S.A., J.P., the Mayor of Newark, was a student of University College, London, and went to Newark 44 years ago as house surgeon to the hospital. He has since practised in partnership in that town, and is now the *doyen* of the profession in Newark and senior honorary surgeon of the hospital. He has done excellent work as lecturer and examiner to the St. John Ambulance Association, and in recognition of his services was appointed Honorary Associate of the Order of St. John of Jerusalem. The Volunteer movement has also commanded his active sympathy. He joined the 4th Notts as surgeon in 1884 and gradually rose to be senior medical officer of the North Midland Brigade, ranking as Brigade-Surgeon-Lieutenant-Colonel. On the formation of the Territorial Forces he was appointed a military member of the County Association and is Lieutenant-Colonel of the Royal Army Medical Corps, T.F., at the present time. He has also received the V.D. The new mayor has been a member of the town council for 19 years and has done good work on the sanitary committee, of which he is chairman, and also in connexion with the isolation hospital. Ten years ago he was unanimously called to the office of mayor, which he filled with success, as is shown by his re-election. Besides being chairman of the free library committee and the museum committee, Mr. Appleby is connected prominently with several educational undertakings in the borough over which he presides.

Oswestry.—Mr. R. de la Poer Beresford, M.D. Glasg., L.R.C.P., L.R.C.S. Edin., L.R.C.P. Lond., V.D., has been elected Mayor of Oswestry after having served his borough in the capacity of medical officer of health for 42 years, which makes him possibly the senior medical officer of health in England. He is the senior surgeon to the Oswestry Hospital and Dispensary and to the Ellesmere Cottage Hospital, and surgeon to the Cambrian Railway Company. He now holds the rank of Colonel, R.A.M.O., T.F., having received his first commission in the Volunteers in 1887.

St. Albans.—Mr. Eustace H. Lipscomb, M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., the Mayor of St.

Albans, commenced his medical training at Caius College and Addenbrooke's Hospital, Cambridge. He subsequently entered Guy's Hospital and after holding a resident appointment at the East London Hospital for Women and Children at Shadwell he joined his father, the late Dr. J. T. N. Lipscomb, and Mr. H. Leslie Bates in partnership in 1888. He has been an honorary medical officer of the St. Albans and Mid Herts Hospital since 1890 and medical officer to H.M. Prison at St. Albans since 1893. On the death of his father in 1898 he was put on the commission of the peace for St. Albans. He is a governor of the St. Albans Grammar School and a trustee of several local charities. It is interesting to note that Dr. Lipscomb's grandfather, Mr. John T. Lipscomb, who died in 1869, was twice mayor of the town—namely, in 1819 and 1836—and that his father was mayor in 1870.

Wolverhampton.—Mr. John Grout, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., the Mayor of Wolverhampton, began his medical career as a pupil of Dr. Russell Talbot, who was at the time medical officer of health of Bow and Bromley. He afterwards entered as a student at Queen's College, Birmingham, and in due course became qualified as L.R.C.P.. L.R.C.S. Edin., after which he commenced practice in Wolverhampton. He joined the town council seven years ago and has always taken a keen interest in municipal affairs. He is a member of several committees and is also a member of the South Staffordshire Small-pox Board. He is one of the honorary surgeons to the Wolverhampton and District Hospital for Women.

MEDICINE AND THE LAW.

The Workmen's Compensation Act.

It is not perhaps surprising that the term "accident" within the meaning of the Workmen's Compensation Act should still be the subject of frequent discussion in the Court of Appeal. In a recent number of the Law Reports there appears a case in which the question was whether a man who died from aortic aneurysm was the victim of an accident. It appeared that while engaged in tightening a nut with a spanner and pressing down the spanner he suddenly fell dead. A post-mortem examination showed that he was suffering from a very large aneurysm of the aorta, that he died from rupture of the aorta, and that the rupture might have been brought about by very slight exertion. county court judge found that death was caused by a strain arising out of the ordinary work of the deceased operating upon a condition of body which was such as to render the strain fatal. It was held that this was an "accident' within the meaning of the Act. In giving judgment the Master of the Rolls said : " Every man brings some disability with him. Any exertion or any external action which might have been entirely innocuous to a man in good health might produce most serious results to a man bringing with him some disability. This man brought with him a disability of a serious nature, an aneurysm, which I quite agree might have caused his death at some time or other without an exertion, usual or unusual. But here we have this facta strain in the course of the ordinary discharge of his duties from which the man dies." Quoting Lord M'Laren, he continued: "If a workman in the reasonable performance of his duties sustained a physiological injury as the result of the work he is engaged in, this is an accidental injury in the sense of the statute." Another case, reported in the same number of the Law Reports, raised the question as to what constitutes "refusal" by a workman to undergo medical examination. The Act provides that a workman who is receiving weekly payments must, if so required by the employer, from time to time submit himself for examination by a duly qualified medical practitioner, provided and paid by the employer. If the workman refuses to submit himself to such examination or in any way obstructs the same, his right to such weekly payments shall be suspended until the examination has taken place. In the case under notice a medical man, instructed by the employers, asked a workman in receipt of weekly payments under the Workmen's Compensation Act to submit himself to examination. The man answered that he had no objection provided his own medical man was present. It was held that he had not "refused" within the meaning of the section. Cases of refusal to submit to operation, where it is advised for the

remedy of the condition, continue to occur, and each such case must bring its own peculiar difficulties. The settled law upon the question whether an injured workman is bound to submit to an operation is well illustrated by a recent case in the Court of Appeal. A seaman had his fingers burnt. One of them became septic. After about four days the ship's doctor lanced it. The next day the same doctor suggested an operation which would have involved two or three incisions being made in the finger. This the applicant refused, with the result that he finally lost the finger. The county court judge was of opinion that the man might have perfectly well undergone the operation, and that he might thus have been cured; but having regard to the fact that another doctor had expressed the view that an operation would not have saved the finger, he could not say that the applicant was unreasonable. In these circumstances he felt bound to make an award which has been affirmed by the Court of Appeal.

The London Hygienic Institute Again.

Comment was made in THE LANCET of Oct. 23rd, p. 1236, upon an action in which damages were recovered against the "London Hygienic Institute" for injuries sustained by a plaintiff, 23 of whose teeth had been extracted at one sitting by an unqualified person employed to practise dentistry by the defendants. Since then yet another action has been brought against the same defendants upon similar grounds, and after being partly heard has been settled upon terms which were not disclosed. This second trial does not seem to demand any further comment upon the methods of the "institute," which appear to have been substantially similar upon the two occasions. In the second case the plaintiff, a woman, had come up from the country to be treated. According to her story an employé of the defendants a man who was not qualified, save by seven years' "experience" in pulling out teeth, advised her to have all her teeth removed and extracted five on the first day, injecting cocaine into her gums, and 11 on the second, after which she suffered severely from cocaine poisoning. The operator in question denied in the witness box that he had advised the extraction of so many teeth at one time and declared that the patient had herself insisted on it. The throwing of the blame on the patient for a matter which should and would be decided by a qualified practitioner is characteristic of this kind of case and the attempted justification employed. The operator's explanation was that the patient desired to have her teeth extracted: that he did not wish to take out so many as 11 on the second day, but that she said that she wished to return home; that he was allowed no discretion; and that, as he was in the hands of his employers, complaint from the patient that he had refused to operate when she was willing to submit would have lost him his situation. He also said that he operated on an average upon 35 patients in a day, working sometimes for 12 hours with an hour's interval, and he excused himself for not having given the plaintiff an antiseptic mouth wash by saying that he had no time to do so, as any delay over a patient meant the prolonging of his day's work. The consideration of the evidence at these two trials is recommended to foolish persons who may think of visiting the "London Hygienic Institute," or any similar establishment where dentistry or medicine is practised by unqualified persons.

OPIUM SMOKING IN CHINA.—Mr. G. M. H. Playfair, British Consul at Foochow, in his annual report to the Foreign Office, after describing reforms that have been effected in educational and other matters, remarks that "another national movement of an extraordinary nature is what rulers and people have done to demolish the national vice of opium smoking. The stimulus came from above in the form of an Imperial edict, but it is doubtful whether even a decree of the Emperor would have done effectual work had not the people shown they were heart and soul in the crusade, and that they were determined the mighty enterprise should succeed. It is still too early to pronounce whether China has succeeded in her endeavour, or, indeed, to be absolutely certain that she is honest in her wish to see the last of the produce of the poppy. But there is, at least in this part of China, evidence that rulers and people are sincere, for streets of opium shops have been closed and myriads of pipes and other smoking paraphernalia have been committed to the flames."

Public Bealth.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Cape Town.—Dr. A. Jasper Anderson is unable to estimate the population of this important city with any degree of accuracy, as great changes have taken place since the date of the last enumeration in August, 1904, but there is no doubt, he thinks, that the population has undergone a decrease. A large number of unmarried Europeans in the prime of life have left the country, and some of the coloured People have gone to other parts of the colony or for German South-West Africa in search of work. Since the census year there has been a gradual decrease in the number of births amongst Europeans each year, and the births for 1908 numbered 791, as compared with 1020 in the census year. There has also been a slight decrease in the number of births amongst the coloured population. Dr. Anderson's rough estimate of the present population of the city is 65,710, the Europeans being a little in excess of the coloured Of course, with this uncertainty as regards the population the several rates must have a greatly impaired value. The birth-rate of Europeans is estimated at 23.29, amongst the coloured population at 51 38, a difference upon which much could be written did space allow. Amongst the Europeans the percentage of illegitimate births to total births was 7.98; amongst the coloured it was 22.79. Turning now to the death-rate, we find that the corrected European rate was 14 16 per 1000, as against a rate of 35 91 for the coloured. The infantile mortality of both white and coloured has very materially diminished within recent years, the average rates for the last four years being 103 3 amongst the Europeans and 227 4 amongst the coloured per 1000 births respectively. Much useful work is being carried out in Cape Town with reference to the control of infantile mortality. Scarlet fever is, Dr. Anderson reports, mainly confined to Europeans, but the coloured are not, it appears, by any means absolutely immune, so far as can be judged from the figures in the report. For instance, in 1908 there were 80 cases with 4 deaths, which is a rather high fatality rate. Dr. Anderson regards the relative immunity of the coloured people as one cause of the spread of the disease; that is to say, the cases are mild and unrecognised, while the difficulty of discovering the rash on coloured skins further accentuates the problem. Puerperal fever claims many victims amongst the coloured population, and Dr. Anderson advises that the midwives should now be registered and regulated. Although tuberculosis is compulsorily notifiable in Cape Town, and the notification appears to be working fairly well, a considerable number of cases both amongst the white and coloured people die unnotified, a circumstance which is explained by the statement that the disease was only discovered just before or after death. Dr. Anderson suggests the foundation of a dispensary where early cases could be diagnosed and assistance rendered. The water-supply of Cape Town is from springs on Table Mountain, but there are still large storage tanks in connexion with each house, of which Dr. Anderson naturally disapproves, and which are soon to disappear. The water at its source is reported to be remarkably pure. Dr. Anderson strongly urges the erection of a municipal abattoir for Cape Town, as by the present arrangement it is impracticable to inspect the meat consumed in the town.

REPORTS OF SCHOOL MEDICAL OFFICERS.

The City of Manchester. - The sixth report of the education committee of this city relates to the year 1907-08; that is to say, to a period antecedent to the operations under the new regulations of the Board of Education. A special interest, therefore, attaches to the report before us in that it shows what the practical people of Manchester, with their strong humanitarian instincts, were doing before Parliament imposed upon the local education authorities the duty of medical inspection. This report, which embodies that of Dr. A. Brown Ritchie, the school medical officer, contains a great deal of information which is of much interest to all social reformers, but we can only touch upon such portions of it which have a direct or indirect bearing upon physical health. Not least amongst these subjects comes that of domestic economy, since it is obvious that no small amount. As to this important but difficult question of treatment, the

of the death- and sickness-rates amongst the poorer classes is due to ignorance as to the dietetic value of foods and as to the proper manner of their preparation. Consequently, it is gratifying to learn that there are now in Manchester three housewifery centres whereat the teaching of cookery, laundry work, and domestic economy to girls is undertaken. During the period to which the report relates 7108 children were under instruction in cooking, 1307 in laundry work, and 192 in housewifery, while practical instruction in the feeding and tending of infants was given to 7267 girls.

Physical exercises under the supervision of an experienced attendant are given to the children in all the schools of the city, and the school playgrounds at several centres are available for the recreation of children out of school hours. The bathing of school children in the public baths is encouraged through an arrangement with the baths committee of the city council, by means of which children from the elementary schools are admitted to the second-class baths without payment when under the charge of a teacher, and free lessons in swimming are given. During 1907-08 as many as 611,612 visits were made by children to the baths, and of these 417,126 were free. The number of visits in 1897 was 133,152. With respect to the provision of country schools for city children, concerning which a good deal is being heard at the present time, it will come as a surprise to many people who have not followed events in Lancashire to hear that such a school was established five years ago by a voluntary committee at Mobberley in Cheshire. The cost of this building was mainly borne by Mr. Herbert Philips of Macclesfield. This school receives relays of children from April to October from the elementary schools in the poorer districts of Manchester and each batch stays about a fortnight, the pupils being accompanied by their ordinary day school teachers, and taught, boarded, and lodged during the period. Nothing is charged except the local habitation of the children. This scheme was approved by the Board of Education about four years ago and the attendances of the children at the county school are duly credited as attendances. Each child pays the nominal sum of 7s. for the fortnight's stay, the balance of the cost being met by voluntary contributions. The experiment has proved a remarkable success, and through the generosity of Mrs. Herbert Philips and others, as well as by the coöperation of the education committee, the dormitories have been extended to accommodate 128 beds, and the site, which has been increased to 17 acres, has been transferred to the city council. Special provision is also made by the education committee for afflicted children, and the report under review contains an instructive account of the details. The actual work of the medical inspection of children under the new regulations only commenced in February, 1909, and the staff now consists of a school medical officer and three male and one female assistant medical officers, each having an allotted district and devoting full time to the work, and, in addition, one male part-time assistant medical officer specially engaged in infectious diseases work. There are also five school nurses one to each medical officer. It is estimated that 18,000 children-i.e., 11,000 of 5 years old and 7000 of 13 years old—out of a total school population of 110,000 will have to be examined during 1909—i.e., during the current year. Although routine medical inspection under the new order of things has but just commenced in Manchester, a perusal of the medical officer's report shows what extremely valuable work has already been carried out in this city in reference to infectious diseases, eyesight, hearing, and the like; while the work done by the school medical officer as regards the provision of meals to necessitous children shows how very markedly the condition of the children has improved with increased sustenance. Lectures on hygiene to pupil teachers were given by the medical officer and lectures to parents were delivered by certain of the school teachers.

The County of East Sussex .- The school medical officer of this district is Mr. A. G. R. Foulerton, the county medical officer of health, while the routine work of inspection is carried out by two assistant medical officers who each contribute a short report upon the work done in their respective districts. These officers devote nine days each fortnight to the duties of routine inspection and the tenth working day to ascertaining at the several schools previously inspected what steps have been taken by the parents to obtain treatment for their children. school medical officer points out that the fact of medical impection in no sense absolves the parent from the duty of obtaining treatment for his child; indeed, as he adds, the position has become emphasised by the subsequent passing of the Children Act, by means of which under Section 12 it is made an offence to fail to make provision for the medical treatment of a person between the ages of 14 and 16 years. As to this Mr. Foulerton observes that in the county here in question the parents may be divided into groups: (a) those who are both able and willing to provide all medical treatment necessary; (b) those who can provide what may be called ordinary treatment, but whose means fail when special treatment is in question; and (o) those parents who are unable to provide any sort of treatment for their children other than that which can be procured under the Poor-laws. For these last children the medical officer regards the voluntary hospitals as providing what is required, and in this connexion he suggests that subscribers to these institutions should place their letters of recommendation at the disposal of the medical inspection sub-committee. Although it may, this medical officer thinks, be advisable to establish school clinics or to provide otherwise for treatment in large cities, such provision in country areas is not necessary. Here in East Sussex the education committee intends to do nothing which will diminish the proper sense of responsibility which the parent should feel for his child.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 7566 births and 4606 deaths were registered during the week ending Nov. 20th. The annual rate of mortality in these towns, which had been equal to 12 0, 13 3, and 13 8 per 1000 in the three preceding weeks, further rose to 14.6 in the week under notice, and exceeded the rate recorded in any week since April last. During the first seven weeks of the current quarter the annual death-rate in these towns averaged 13.0 per 1000, and in London during the same period the rate did not exceed 12.8 per 1000. The lowest annual rates of mortality recorded in the 76 towns last week were 6.5 in Hornsey, 6.7 in Burton-on-Trent, 8.2 in Reading, and 8.6 in Bournemouth; the rates in the other towns. ranged upwards, however, to 20.8 in St. Helens, 21.1 in Birkenhead, 21.8 in Bootle, and 26.5 in Hanley. In London the recorded death-rate last week was equal to 14.7, showing a further increase upon the rates in recent weeks. The 4606 deaths registered in the 76 towns last week showed a further increase of 253 upon the numbers returned in the three preceding weeks, and included 281 which were referred to the principal epidemic diseases, against numbers steadily declining in the 12 preceding weeks from 849 to 261; of these 281 deaths, 73 resulted from diarrhoea, 69 from whoopingcough, 47 from diphtheria, 45 from measles, 28 from scarlet fever, and 19 from "fever" (principally enteric), but not one from small-pox. The 281 deaths from these epidemic diseases last week were equal to an annual rate of 0.9 per 1000, against 0.9 and 0.8 in the two previous weeks. No death from any of these epidemic diseases was registered last week in Reading, Devonport, King's Norton, Newport (Mon.), Bournemouth, or in four other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2.7 in Merthyr Tydfil, 3.0 in West Bromwich, 3.2 in Northampton, and 3.8 in Hanley. The deaths attributed to diarrhoea in the 76 towns, which had declined in the 12 preceding weeks from 675 to 68, rose again last week to 73; the highest annual death-rates from this cause last week were 1 3 in Merthyr Tydfil, and 1.8 both in Aston Manor and in South Shields. The fatal cases of whooping cough, which had been 31 and 48 in the two preceding weeks, further rose last week to 69, and caused annual rates equal to 1.3 in Coventry and 1.5 in Middlesbrough. The 47 deaths from diphtheria also showed an increase, and included 16 in London and its suburban districts, 6 in Liverpool, 3 in Manchester and Salford, 3 in Bradford, and 2 both in Stockport and in Warrington. The 45 fatal cases of measles exceeded the number in any recent week, and caused the highest annual rates, equal to 3.0 in Hanley and 3.2 in Northampton. The 28 deaths from scarlet fever were fewer than in any recent week; 7 occurred in Birmingham, 6

in Manchester and Salford, and 2 in Bury, which were equal to an annual rate of 1.8 per 1000. The 19 deaths referred to "fever" were within one of the number in the previous week, and included 3 in Leeds. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had declined during the five preceding weeks from 2810 to 2624, had further fallen on Saturday last to 2606; 308 new cases of this disease were admitted to these hospitals during last week, against 336 and 284 in the two preceding weeks. The Metropolitan Asylums Hospitals contained 5 small-pox patients on Saturday last, an increase of of the 1363 deaths registered in London last week. Of the 1363 deaths registered in London last week, 283 were referred to pneumonia and other diseases of the respiratory system, against numbers increasing from 167 to 288 in the five preceding weeks; these 283 deaths were, however, 47 below the corrected average number in the corresponding week of the five years 1904-08. The causes of 40, or 0.9 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered last week were duly certified in London, Leeds, Bradford, Newcastle-on-Tyne, Hull, Nottingham, Leicester, and in 49 smaller towns; the 40 uncertified causes of death in the 76 towns last week included 8 in Birmingham, 5 in Liverpool, and 4 both in Sheffield and in South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 768 births and 708 deaths were registered during the week ending Nov. 20th. The annual rate of mortality in these towns, which had been equal to 12.9, 15.3, and 15.8 per 1000 in the three preceding weeks, further rose to 19 8 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these Scotch towns averaged 14.5 per 1000, and exceeded by 1.5 the mean rate during the same period in the 76 largest English towns. The annual death-rates last week in these Scotch towns ranged from 11.0 and 14.8 in Leith and Edinburgh, to 17.6 in Paisley and 24.9 in Glasgow. The 708 deaths from all causes in the eight towns last week showed a further increase of 142 upon the numbers returned in the three preceding weeks, and included 77 which were referred to the principal epidemic diseases, against 67 and 66 in the two previous weeks. These 77 deaths were equal to an annual rate of 2.2 per 1000; the mean rate from the same diseases last week in the 76 English towns did not exceed 0.9 per 1000. The 77 deaths from these diseases in the Scotch towns last week included 36 from messles. 12 from whooping-cough, 10 from diarrhea, 9 from scarlet fever, 9 from diphtheria, and 1 from "fever," but not one from small-pox. The fatal cases of measles which had been 9, 24, and 22 in the three preceding weeks, further rose last week to 36, of which 34 occurred in Glasgow and 2 in Edinburgh. The 12 fatal cases of whooping-cough also showed an increase upon the numbers in recent weeks, and included 10 in Glasgow. The deaths attributed to diarrhoea, which had been 10, 13, and 16 in the three preceding weeks. declined again last week to 10, of which 3 were returned both in Glasgow and in Aberdeen, and 2 in Dundee. Seven of the 9 fatal cases of scarlet fever occurred in Glasgow; and the 9 deaths from diphtheria included 7 in Glasgow and 2 in Edinburgh. The death from "fever," certified as cerebro-spinal fever, and occurred in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 68, 108, and 115 in the three preceding weeks, further rose to 195 last week, and exceeded by 59 the number registered in the corresponding week of last year. The causes of 27, or 3.8 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,142,308 persons, 596 births and 439 deaths were registered during the week ending Nov. 20th. The mean annual rate of mortality in these towns, which had steadily increased in the four preceding weeks from 14.8, to 19.2 per 1000, further rose to 20.0 in the week under notice.

* Including membranous group.

During the first seven weeks of the current quarter the annual death-rate in these Irish towns averaged 16.9 per 1000, whereas the mean death-rate during the same period did not exceed 13.0 in the 76 largest English towns, and 14.5 in the eight principal Scotch towns. The annual death-rate last week was equal to 23.6 in Dublin (against 14.7 in London), 18.1 in Belfast, 21.9 in Cork, 23.0 in London-derry, and 17.8 in Limerick; the mean rate in the 16 smallest of the Irish town districts last week was equal to 18.5 per 1000. The 439 deaths from all causes in the 22 town districts last week showed a further increase of 10 upon the numbers in the four preceding weeks, and included 18 which were referred to the principal epidemic diseases, against 26, 21, and 20 in the three preceding weeks; these 18 deaths were equal to an annual rate of 0.8 per 1000; in the 76 English towns the mean rate from the same diseases last week was 0.9, and in the eight principal Scotch towns was 2.2 per 1000. The 18 deaths from these epidemic diseases in the Irish towns last week included 7 from diarrhæa, 6 from whooping cough, 3 from diphtheria, and 1 each from scarlet fever and "fever" (enteric), but not one either from measles or small-pox. The 7 deaths attributed to diarrhoea showed a further decline from the numbers in recent weeks, and included 2 both in Dublin and in Belfast. The 6 fatal cases of whoopingcough exceeded by 1 the number in the previous week; 4 occurred in Belfast and 2 in Dublin. Of the 3 deaths from diphtheria, 2 were returned in Dublin and 1 in Newtownards. The fatal case of scarlet fever occurred in Belfast, and that of enteric fever in Cork. The deaths referred to pneumonia and other diseases of the respiratory system, which had steadily increased from 50 to 88 in the four preceding weeks, further rose to 110 last week. The causes of 14, or 3.2 per cent., of the deaths registered in these Irish towns last week were not certified by a registered medical practitioner or by a coroner; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.9 per cent., and in the eight Scotch towns the proportion was 3.8 per cent.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1909.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6.5 per 1000 of the population, estimated at 4,833,938 persons in the middle of the year; in the three preceding months the rates were 6.4, 5.0, and 7.1 per 1000 respectively. The lowest rates last month were recorded in Kensington, Hampstead, Stoke Newington, Holborn, the City of London, and Wandsworth; and the highest rates in Paddington, Finsbury, Bethnal Green, Stepney, Lewisham, and Woolwich. During last month 4 cases of small-pox were notified, of which 3 belonged to Stepney and 1 to St. Pancras. The prevalence of scarlet fever showed a marked decline last month; among the several metropolitan boroughs this disease was proportionally most prevalent in Paddington, Bethnal Green, Poplar, Lambeth, Lewisham, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month was 2708, against 2628, 2329, and 2717 at the end of the three preceding months; the weekly admissions averaged 325, against 358, 274, and 394 in the three preceding months. Diphtheria was slightly more prevalent than it had been in the preceding month; this disease was proportionally most prevalent in Finsbury, Shoreditch, Deptford, Lewisham, and Woolwich. Metropolitan Asylums Hospitals contained 958 diphtheria patients at the end of last month, against 890, 795, and 901 at the end of the three preceding months; the weekly admissions averaged 119, against 107, 83, and 119 in the three preceding months. The prevalence of enteric fever showed a decline last month; the greatest proportional prevalence of this disease occurred in Holborn, Finsbury, Stepney, Poplar, and Battersea. There were 78 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 60, 55, and 75 at the end of the three preceding months; the weekly admissions averaged 11, against 7, 10,

and 13 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, and Southwark. The 19 cases of puerperal fever notified during the month included 3 in Wandsworth and 2 in Poplar. Of the 2 cases notified as cerebro-spinal meningitis 1 belonged to Battersea and 1 to Greenwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending Oct. 30th the deaths of 4197 London residents were registered, equal to an annual rate of 11.3 per 1000; in the three preceding months the rates were 10.2, 10.5, and 11.5 per 1000. The lowest death-rates last month were 6.9 in Hampstead, 8.8 in Lewisham, 9.2 in Wandsworth, 9.3 in Deptford, and 9.6 in St. Marylebone and in Woolwich; the highest rates were 13.8 in Stepney, 13.9 in Bethnal Green, 14.1 in Southwark, 15.4 in Shoreditch, 15.6 in Bermondsey, and 16.0 in Finsbury. The 4197 deaths from all causes included 325 which were referred to the principal infectious diseases; of these, 1 resulted from small-pox, 32 from measles, 28 from scarlet fever, 38 from diphtheria, 44 from whooping-cough, 15 from enteric fever, and 167 from diarrhoea. The lowest aggregate death-rates from these diseases last month were recorded in Paddington, Westminster, Hampstead, St. Pancras, Stoke Newington, Holborn, Wandsworth, Deptford, and Lewisham; and the highest rates in Fulham, Finsbury, Shoreditch, Bethnal Green, and Poplar. The fatal case of small-pox belonged to Stepney. The 32 fatal cases of measles showed a decline of 25 from the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Stoke Newington, Shoreditch, Bethnal Green, Stepney, and Poplar. The 28 deaths from scarlet fever were 23 fewer than the corrected average number; the greatest proportional mortality from this disease was recorded in the City of Westminster, Islington, Bethnal Green, Bermondsey, Lambeth, and Lewisham. The 38 fatal cases of diphtheria showed a decline of 14 from the corrected average; the highest death-rates from this disease were recorded in Hammersmith, Fulham, Chelsea, Shoreditch, Stepney, and Southwark. The 44 deaths from whooping-cough were slightly fewer than the corrected average number; this disease was proportionally most fatal in Shoreditch, Bethnal Green, Stepney, Poplar, Southwark. Deptford, and Woolwich. The 15 deaths from enteric fever were less than one-half of the corrected average number, and included 2 belonging to Paddington, 2 to St. Pancras, and 2 The 167 fatal cases of diarrhoea were 115 to Battersea. below the corrected average number; this disease was proportionally most fatal in Fulham, Finsbury, Shoreditch, Bethnal Green, Poplar, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 37.3 per cent. below the average.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 118 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Hampstead, Holborn, the City of London, Deptford, and Woolwich; and the highest rates in Kensington, Hammersmith, Finsbury, Shoreditch, Bethnal Green, Poplar, and Bermondsey.

PRESENTATION TO A MEDICAL MAN.—In addition to the case of eye instruments, field glass, and fountain pen presented to Mr. Randal Herley by members of the different departments of the Dewsbury and District General Infirmary, which we announced in The Lancet of Nov. 20th, p. 1558, our attention has been called to the fact that the members of the board added to the presents a large ophthalmic trial case.

Donations and Bequests.—The secretary of the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, has received two anonymous gifts, one of £5000 to the special jubilee fund, and one of £2000 for the general fund.—Mrs. Wheeler has made a gift of £600 to the Earl of Beaconsfield Memorial Cottage Hospital at High Wycombe, in memory of her husband, the late Mr. Robert Drew Wheeler.

THE SERVICES.

ARMY MEDICAL SERVICE.

Colonel Owen E. P. Lloyd, V.C., to be Surgeon-General, vice W. Donovan, C.B., retired (dated Nov. 17th, 1909). Brevet-Colonel Tom P. Woodhouse, from the Royal Army Medical Corps, to be Colonel, vice O. E. P. Lloyd, V.C. (dated Nov. 17th, 1909).

ROYAL ARMY MEDICAL CORPS.

Lieutenant Colin Cassidy is seconded for service with the Egyptian Army (dated Oct. 14th, 1909).

INDIAN MEDICAL SERVICE.

If The King has approved of the following promotions among officers of the Indian Medical Service:—Majors to be Lieutenant-Colonels (dated Sept. 30th. 1909): Henry Bruce Melville, Joseph Charles Stoelke Vaughan, Alexander Leonard Duke, Joshua Chaytor-White, John Blackburn Smith, Henry Francis Cleveland, and Charles Henry Bedford. Lieutenant to be Captain (dated Sept. 1st, 1909): Shumshere Singh.

The King has approved of the retirement of the following officer:—Lieutenant-Colonel Julian Carter Carington Smith (dated August 7th, 1909).

TERRITORIAL FORCE.

Royal Army Medical Corps.

Eastern Mounted Brigade Field Ambulance: Meredith Sedgwick Doubble to be Lieutenant (to be supernumerary) (dated Oct. 30th, 1909).

London Mounted Brigade Field Ambulance: Major Martin Alfred Cooke, from the list of officers attached to units other than Medical Units, to be Major (dated June 20th, 1909).

Highland Mounted Brigade Field Ambulance: John Macpherson Grant to be Lieutenant (dated Oct. 19th, 1909).

3rd London (City of London) Field Ambulance: Lieutenant George L. L. Lawson to be Captain (dated August 22nd, 1909).

Attached to Units other than Medical Units.—Lieutenant-Colonel and Honorary Surgeon-Colonel Robert L. Sparrow resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Oct. 31st, 1909).

THE SPANIARDS IN MOROCCO.

In the *Times* of Nov. 18th a special correspondent at Melilla, telegraphing on Nov. 17th, describes the hospital administration, which he says it is impossible to praise very highly. The main base hospital is at Malaga, where all, except dangerous cases, are shipped. At the advanced base hospital at Melilla the accommodation is inadequate. With the exception of the base accommodation and the forwarding of cases, the treatment of the sick and wounded is good and the surgery is beyond reproach. There has been much enteric fever, pneumonia, and dysentery, but malaria has not been so prevalent as was anticipated.

DEATHS IN THE SERVICES.

Deputy Inspector-General Thomas Secombe, R.N. (retired), at his residence in Granville Mansions, Torquay, on Nov. 19th, in his ninety-first year. He entered the Royal Navy as assistant surgeon in 1845, became staff-surgeon eight years later, and in 1867 was promoted to fleet-surgeon. In 1880 he retired with the rank of deputy inspector-general of hospitals and fleets. The deceased officer served as surgeon to the native levies during the Kaffir War of 1851; he was present at almost all of the skirmishes of this campaign (Kaffir medal). He was in charge of the field hospital at the taking of Rangoon (Burmese medal), and he also served in several of the boat campaigns (mentioned in despatches).

Lieutenant-Colonel Frederick James Crawford, I.M.S., on board the steamer *Herefordshire*, near Suez, on Nov. 5th, aged 45 years. He entered the service as assistant surgeon in 1887 and reached the rank of lieutenant-colonel in 1907. He was the principal of the Madras Medical College and had been district surgeon of Ganjam.

Correspondence.

"Audi alteram partem."

OSTEITIS DEFORMANS.

To the Editor of THE LANCET.

SIR,-In THE LANCET of Nov. 13th is an annotation on the subject of "Osteitis Deformans," wherein it is stated "that Sir James Paget first described that form of chronic inflammation of the bones which bears his name." in the year 1876, and his paper may be found in the volume of the Medico-Chirurgical Transactions of the following year. He described it as a rare disease and spoke of it as the first which had been under his care. He then gave an account of it and added others from various sources, and amongst them was one of my own in which I had taken specimens of the bones to the Pathological Society. The account is to be found in the Pathological Transactions for the year 1869. I called the case "osteoporosis," or spongy hypertrophy of the bones. I so named it because it was the word on the labels attached to some old specimens in the museum of Guy's, and which evidently belonged to a case of this disease, shown by the enormously thickened skull and the large and crooked long bones of the limbs. In giving my lectures in 1857 I commented on these bones and said I did not think they arose from an inflammatory process because I could find no new osseous tissue either on their surface or interior, and therefore I considered the name to be most excellent. I believe it was also used on the continent. When, therefore, an example of the same disease came under my own notice I called it "osteoporosis," and more especially as I discovered no new osseous tissue either as ostitis or periostitis. I think now a better name would be "osteoporosis deformans." I may add that in the second edition of my book on pathological anatomy I gave a description of this case. This was two years before the appearance of Paget's paper. I have given these particulars because this different name is the sole cause of my writing this letter. The patient came under my care from being called in by a medical man at Camberwell. The patient, a gentleman, aged 60 years, had consulted all the leading men in London, and he had also visited me. When he was too ill to leave home I was asked to see him occasionally. After his death his friends, knowing it was a rare and important case, gave me carte blanche to take away some of the bones for examination.

The report in the Pathological Transactions says that the post-mortem examination was made on Jan. 13th, 1869, and that I was assisted by Mr. Goodhart, house physician of Guy's Hospital, and he it was to whom I am indebted for the long description which he gave me. I wrote a few days ago to Dr. Goodhart at Portland-place, and he answers me on Nov. 14th by saying, "I remember the case well. I made the 'post-mortem' somewhere down in Camberwell with a man named Massey, and I brought away the vault of the skull, a femur, and some other things which ought to be in the museum. There are specimens in Guy's museum long before our time, and Paget summed up all the cases and called the disease 'osteltis deformans.'"

I may be allowed to say in conclusion that personally the question of originality is of very little moment and of no importance to most medical men, but there are those who are bibliographers and historians who would altogether miss the first account of the disease if they looked for its usual name. I am also instigated in writing for the sake of Dr. Goodhart, who was the first who carefully examined the bones and their structure, giving also their measurements and weights. I may add that Dr. Goodhart is quite ignorant of my writing this letter. I trust also that the throught will not arise in anyone that I am suggesting a dishonourable act on the part of Sir James Paget, for this would have been impossible for my old friend; indeed, his method was the usual one and the most correct—to take a number of cases of a remarkable disease, discuss its nature, and give it, according to his views, the most apposite name.

I am, Sir, yours faithfully,

SAMUEL WILKS.

Hampstead, Nov. 20th, 1909.

BRAIN AND MIND.

To the Editor of THE LANCET.

SIR,-I do not think Dr. Mercier's article on the above subject gets quite down to the fundamental problem. Brain is ultimately "matter" and mind is "mind." We do not, as Dr. Mercier says, know whether matter is real or is only an assumption, but for practical purposes we are bound to assume its reality. Accepting the assumption we are bound to agree to Hobbes's dictum that our senses are affected only by motions of matter, or perhaps more simply by motion. All speculations and judgments by which we reduce things to categories are therefore inferences from the stimulus of motions, the only perceptible differences being the diverse modes of the motion which impinge upon us. Natural science is pre-eminently the classification of impinging motions and generalisations based thereupon. One of these generalisations is our concept of "life."

Physics, including chemistry, reveals the law of proportion as between causes and effects; given the components the resultant can be calculated in advance; the motions of matter are one vast phenomenon of absolute mechanical predestination. But we also observe certain motions of matter which can only be regarded as evidence of self-determination; certain masses of matter exhibit motions which tend to self-preservation and are not accurately calculable. We say that the lumps of matter which exhibit this mode of motion are "alive." We might formally define the phenomena of life as "self-determined motion." But self-determination is flatly contradictory to the physical large of motion and so the definition is a contradiction laws of motion, and so the definition is a contradiction in terms: it is nonsense, or perhaps better, paradox. And yet it is true to the facts. The three hypotheses described by Dr. Mercier are, if this be right, merely attempts to reduce to logically consistent language phenomena which can be described only in terms of paradox. Such

attempts are necessarily doomed to failure.

The special phenomenon of a differentiated nervous system seems to me to be an irrelevancy. The neurons are only cells so shaped that juxtaposition to certain other cells can be attained in spite of anatomical distance. The problem of the relation of self-determination to material motion is essentially an intra- not an intercellular problem, and therefore is the same in a protozoon as in a vertebrate, and it would seem that the protozoon would be the better type to study on account of its simplicity, supposing the difficulties to lie in the phonomena. But it seems to me that they do not, but that the difficulty is subjective. "Mind" and "matter" or self-determination and motion are subjectively distinct and irreconcileable categories. Monists assert that they meet in a higher category, but that category has not yet been described. However, although we can have no inkling of the relation of these paradoxical phenomena (calling some of them "epiphenomena" seems to me no help at all), we know that there is relation. We know that mind can disturb the predestined order of motion, and that motion can affect mind; and within certain limits we know what the effect will be. We may therefore discover empirically the motions of matter which will impinge beneficially on a disordered mind, and the mental states which have an integrating effect on a disordered body. This for practical purposes is all we want to know.

Therapeutics is a sensible science not too proud to work machinery whose laws it does not understand.

I am, Sir, yours faithfully,

F. CLAUDE KEMPSON, M.B. Cantab. Demonstrator of Anatomy in the University of Cambridge

Manea Vicarage, March, Cambs., Nov. 15th, 1909.

To the Editor of THE LANCET.

SIR,—On reading Dr. Charles Mercier's interesting article in THE LANCET of Nov 13th it occurred to me that the attention of psychologists might be advantageously directed to the following suggestions as to the relation of matter to

It has been suggested that the brain is the organ by which the mind can "appreciably" affect matter. Might I by analogy explain what is meant? Take magnetism. If we had no iron, nickel, or cobalt available in this world the knowledge of magnetism would have been much less developed, because the earth's magnetism is not "appreciable"

to our unaided senses; a piece of copper, for instance, showing no appreciable change when rotated in the earth's magnetic field. It is perfectly practicable, however, by means of drawing out the copper to a fine wire and constructing with it various coils 1 to demonstrate to anyone the fact that the earth is a magnet. Thus we see that arrangement of material raises "inappreciable" effects to "appreciable"

Again, our skin is not conscious of light (heat rays should be removed by solution of alum screen), although there is a reaction, for pigment is slowly deposited. That is to say that light is not "appreciated" by our skin. The retina however, on account of its "peculiarity" of chemical and physical structure is able to appreciate light without artificial aids. Again, it is the chemical and physical constitution of certain cells in the tongue which enable taste to be "appreciated." We cannot taste with our hands! The same with sense of smell. Taking these last two senses, no other of our senses can discriminate the molecular constitution of substances, but the "peculiar" chemical and physical arrangement of "smell organ" and "taste organ" not only enables minute, almost incalculably small, particles of matter to be differentiated and their nature recognised, but renders even the internal arrangement of a molecule to be "appreciable." I may instance the different odours of the ortho-, meta-, and para-compounds, only differing in the positions of identical side-chains of the benzenering compounds.

Have I said enough to make clear the following-namely, that the brain with its "peculiar" chemical and physical constitution may be the organ for rendering "appreciable' the action of mind? Mind may be an existing "something." whether of the nature of light or magnetism or of attenuated matter. Perhaps there is a so-called "soul" which may be a perfectly real existing thing which, however, is not "appreciable," or rather does not "appreciably" affect matter except when the "peculiar" chemical and physical structure, the brain, is able to be affected, and when the nerves and muscles are functionally connected with the brain. Thus, magnetism is existent and all matter is affected minutely by magnetism, but it is only three metals and certain physical arrangements of other metals which

render magnetism "appreciable."

Again, light is existent and all matter is affected more or less, but it is the chemical and physical structure of the retina which renders it "appreciable." By analogy it is suggested, therefore, that the soul may be a thing which is in relation with the physical universe and probably can affect all matter to a very slight degree, but that as the brain has developed through the ages, its function as the "mind organ" has been the "motif," or, in other words, the path of progress. I myself would take the beginnings of the "mind organ" back to a very remote period as by analogy we refer the beginnings of our "light organ" to the black spot on the the amphioxus.
I am, Sir, yours faithfully,
R. O. T. EVANS. nervous system of the amphioxus.

Herne Bay, Nov. 14th, 1909.

To the Editor of THE LANCET.

SIR, -Dr. Mercier's article on this subject is very interesting, and, as a peaceless practitioner, one wishes for the time to treat all its many points with the thoughtful and critical consideration that they call for. The three cases that he claims as being on all fours, are they not rather at sixes and sevens? Dr. Mercier would have us believe that the colour of an object is not part of the object. Really the word "colour" stands for two separate facts. It has been supposed that colour means only the sensation caused by those attributes of any substance which produce the effects of red, green, &c., in the mind. But because we understand the method of the transmission of rays producing the sensation of blue, and because we know much of the mechanism of the organ concerned in the receptivity and something, too, of the organ employed in the interpretation of those rays, because we have some understanding of these things, what right have we to say that a lapis lazuli is not innately, intrinsically, and of itself in every degree of light of a blue colour whether it be beheld or not?

¹ A delicate galvanoscope can be constructed by suspended coils, no magnetic needle being required.

2 See experiments by Professor and Mrs. Ayrton.

It does not follow that because in respect to our know-ledge of a phenomenon we can point to a plus sign that therefore there exists as a consequence of that knowledge a minus sign in any portion of that phenomenon. The object is none the less coloured because we know the method of its appeal to the senses. The colour of an object (i.e., those attributes compelling the eye to a cognition) is undoubtedly in the object; the name of it, its memorial associations, and the accident of its observation only, belong to the individual seeing the object. Dr. Mercier means by colour apparently the phenomena of cognisance, whereas the word used to be, and may legitimately yet be applied to that characteristic of an object which compels its cognisance.

Is mind a function of the brain? Assuredly it is one of the functions of the neurons which make up the essential and distinctive part of the brain. Mind—which is perhaps more accurately and better expressed by the word "mentation." which, carrying with it fewer connotations, is therefore less confusing—has never been proved to exist apart from protoplasmic matter. Nothing like the same amount of proof is forthcoming with regard to mentation unconnected (in its origin and manifestation) with matter as exists of the intimate connexion of mentation with protoplasm. As regards the existence of mind apart from matter, the whole gamut of mental and physical phenomena has been gone through time and time again, without even the fourth-rate success of inferential proof drawn from the admittedly weak process of reasoning by analogy.

The importance of the absolute necessity of neurons to the phenomenon of mentation is in no way weakened by the fact that neurons perform duties which cannot be spoken of as mind effects. If Dr. Mercier admits that neurons functionate by receiving, storing, and liberating motions, and that, a step further, they do these things in a discriminatory manner, where is the difficulty in admitting several steps further in development-viz., the mentation of the lower animals? Admitting this, there can be no difficulty in associating the highest efforts of mentation with neurons, and with neurons alone. Certainly, the mentation of a Shakespeare is a different thing from the mentation of a low vertebrate. but the difference is only a difference in the degree of complexity. Given a higher complexity of tissue—a complexity which may be so infinitesimal in its details as to be unrevealable by any method at present at our disposal—a functional complexity must result which, increasing dynamically, may be even more distant from whatever unit might be adopted than 999 to the 999th power is from 1. A difference in the degree of complexity does not necessitate such a difference in kind as is implied when one admits discriminatory functioning of the neurons, but disallowing mentation as a functioning of the same nervous structures classes it as a universe to itself. Ex nihilo nihil fit, and if mind (or the mentation process) be disparate from all material things, whence does it originate? What platform does it operate from? If the brain be its station of arrival, where may we look for the station of departure, and by what lines has it travelled from the terminus it set out from?

The idea that mind is a thing apart from, and entirely independent of, matter owes its ready and unquestioned acceptance because it harmonises somewhat with the faith we have inherited from our forefathers. The scientific method is to work from the known to the unknown. It is unscientific (though as a metaphysical exercise highly entertaining) to form first a theory based in this instance on the crude theologies of early civilisations and then endeavour to handle facts so that they may support the hypothesis that harmonises best with these assertions of crude primal folkfaiths. The method that offers the most certain solution of the problems of brain and its mentation processes is to study them with the idea that mentation is a highly specialised nervous action, that nervous action is a function of neurons. that neurons are protoplasmic masses of a particular structure, and that the action or function which invariably accompanies that structure is due to that structural peculiarity. The proposition that mind is the resultant of structural peculiarity and environmental adaptation of certain elements in chemical and mechanical combination has never received its due attention as a working hypothesis. When propounded by the more matter of fact and practical of the school of materialists it was received with as much withering (if only scornful) treatment as Galileo had meted out to him. It may prove eventually to be the main index to that explanation of the connexion of mind with matter which Dr. Mercier somewhat pessimistically says will in all likelihood never be known.

Points which need working out in connexion with protoplasm are the proportions of negative and positive particles of electricity, the allotropic modifications of the elements composing protoplasm, the facetting of the molecules and possibly of the ions, the unexplored chemical combinations of carbon with water, &c. Any of these or all in varying degrees may be intimately and particularly concerned in the processes of mentation. The field which, however, offers the greatest finds for the present is subconscious mentation, the automatic digestion of facts without any conscious participation. In the meantime, while these fields are being worked, let us discuss the interesting points with which Dr. Mercier's article teems.—I am, Sir, yours faithfully.

J. Hambley Rows, M.B., C.M. Aberd. Bradford, Nov. 20th, 1909.

THE THERAPEUTICS OF SUGGESTION. To the Editor of THE LANGET.

SIR,—I was much interested to find that in your recent remarks on the therapeutics of suggestion 1 you so definitely differentiated between "suggestion" and "persuasion" as practical therapeutic agents—a differentiation which is apparently endorsed by Dr. Alexander Morison in his philosophic letter last week, where he speaks of the benefit to be derived from "the plain if sympathetic inculcation of common sense, the inspiration of righteous conduct, and, above all, of courage to face and to accept whatever betide." For personally I cannot help thinking that no such distinction would ever be made by anyone accustomed to deal with these mental factors as a matter of everyday routine, and for the following reasons.

Persuasion consists of a verbal appeal to a patient's mind by which he is eventually convinced that certain ideas he has held are errogeous, and consequently alters his outlook on life and his conduct accordingly; it is thus pre-eminently suited to the treatment of abnormal mental states, such as are associated with psychasthenia and very early in-Thus a man who has a growing notion that his sanity. friends are conspiring against him, or that his life and work are valueless, may be persuaded by persistent argument that such ideas are erroneous, and be actually saved from the threatening breakdown by a series of conversations conducted with a definite therapeutic object. I have seen such things done. And what happens under these circumstances is that a new idea is insinuated into the patient's mind which either dominates or overcomes the pathological one. Now this satisfies the definition of "suggestion," and I therefore argue that "persuasion" does not essentially differ from "suggestion," but is merely that form of suggestion which is most suitable for use in the treatment of certain mental conditions. On the other hand, supposing that one has to deal with pain of functional origin, we know that it is useless to try to persuade the patient that the pain is not there; if a patient says he has a pain in his head, for example, experience tells us that we cannot under ordinary circumstances persuade him that he has not. But it is well known to those who have any practical knowledge of suggestive therapeutics that some pains can be relieved by an appeal to the patient's mind either by confidently spoken words, or through the stimulus of, say, a mild faradic current; the curative idea being thus suggested to the patient, whose mind is to all intents and purposes persuaded to accept the idea of freedom from pain.

If I may so put it, I think that both the writer of your remarks on the therapeutics of suggestion and Dr. Alexander Morison have meant to express the same thing, but have confused the issue through unfamiliarity with the technique of suggestive therapeutics. And what they have intended to express is, I think, that an indirect appeal to the patient's higher faculties, as, for example, through the medium of a conversation, is much to be preferred to anything in the nature of a "sitting" or "séance" in which the patient has to come into more than ordinarily lose relations with the physician, or in which various manual manipulations play a

leading part, and with such a view I am entirely in accord. But I must point out that, with the exception of some mental conditions, unless such an appeal is accompanied by some material form of treatment it will fail in most cases. I am stating this as a matter of practical experience, not of theory. Moreover, there is no reason why the material means used to support the suggestion should not be such as to possess a therapeutic efficacy of its own; indeed, I have repeatedly upheld the view that it is in such combinations that suggestion should find its rational place in our therapeutic armoury.

The mystery with which suggestive therapeutics is often surrounded, the induction of the hypnotic state which is by some considered to be an essential accompaniment of suggestion in treatment, the laying-on of hands and other manipulations in use, all act in the same way, I believe—namely, by impressing the patient with the idea that he is being subjected to some extraordinary curative force, and so strengthening in this way the suggestions made, not by any specific virtues of their own. And if the same result can be brought about, as I am quite satisfied that it can be, by methods more in accordance with our notions of what a medical man's work should be, I think that most practitioners will be in agreement that it is time that the more mysterious, and indeed more doubtful, adjuncts of suggestive therapeutics were dropped once and for always.

It is my hope that those who have at heart the development of the better side of suggestive therapeutics, not as a specialty or specific but as an adjunct of routine treatment, will come forward in support of the views I am here expressing, and which have, I think, in intent been expressed both in your valuable comments on the subject and in Dr. Morison's letter.

I am, Sir, yours faithfully,

EDWIN L. ASH, M.D. Lond.
Harley-street, W., Nov. 21st, 1909.

OXALURIA.

To the Editor of THE LANCET.

SIR, -In THE LANCET of Nov. 6th there was an interesting paper by Dr. R. Maguire upon this subject, and a large part of it is taken up with the endeavour to prove that the condition when mild is due to "a disorder in metabolism," "an accident or incident in the metabolism of carbon," but when more severe to "an exaggerated production accompanied by nervous and dyspeptic symptoms," and he cites a case which he thinks supports his hypothesis, but I would suggest that there is not much which bears it out, and that the oxaluria can be explained in another way. Anyone who frequently examines urinary deposits with the microscope will know how very commonly crystals of oxalate of lime are found, and these are not always (as Dr. Maguire himself allows) accompanied by nervous and dyspeptic symptoms even in the severe cases where oxalic calculi form. In my experience in a general practice such symptoms are quite uncommon; the one complaint which patients sometimes make in the cases without calculi is slight pain in the course of a ureter; as a rule, there is no other sign of ill-health, even in calculous cases. Therefore, oxaluria and dyspepsia may occur separately or together, and when together I believe they are a coincidence and not cause and effect, and my reason for this belief is that in my clinical experience the urine can always be cleared of oxalate crystals by attention to diet alone in a few days. Put the patient on an oxalate-free diet and the urine will soon become free from oxalate Dr. Maguire mentions that his patient was not relieved by a three weeks' stay at Vichy, but then his diet was composed mostly of vegetables! Not much improvement was to be expected. (By-the-bye, I suppose he was put upon a vegetable diet as a result of the pernicious theory that oxalic acid in the urine is a result of a decomposition of uric acid.) But Dr. Maguire later ordered rest, a change of diet and dilute nitric acid, and the deposit of calcium oxalate in the urine lessened, as he says, "almost pari passu with the improvement in digestion," but also, be it noticed, it coincided with a change to a liberal diet of white meat"—that is, to a more oxalatefree diet. It seems to me that in his case the dyspepsia was due to "mental and physical fatigue," "great overwork, anxiety, and sleeplessness," and the oxaluria was due to error

in diet; at any rate, no other hypothesis as to "a disorder in metabolism" is required.

I am, Sir, yours faithfully,

Leicester, Nov. 9th, 1909. REGINALD PRATT, M.D. Lond.

CIVILISATION AND THE CORSET.

To the Editor of THE LANCET.

SIR,—The attention which Mr. W. Arbuthnot Lane has drawn to the benefits of corsets is particularly pertinent, because for some years past they have been strenuously decried by certain exponents as being detrimental to muscular development and to liberty of limb. The fact is, women have found by centuries of accumulated experience that corsets are to them structurally indispensable, whilst modern science has also shown that they are physiologically beneficial.

The women of Egypt, of Greece, and of Rome all wore corsets, and did so for service and not for fashion. These ancient corsets consisted of three parts. First, there was the loin band or zone, which was the essential piece, and was persistently worn; then there was the thoracic band or strophion, which gave mammary support as required; and, lastly, there was the waistband, which intermediated between the other two. It is the conjunction of these three pieces that has given rise to the present corset, in which it is still the loin portion that is indispensable, whilst the other parts are merely adjunctive. And not only have women in all ages and in all climates found the "girding of the loins" to be a necessity, but even men in sultry and atonic countries have acted, and still act, similarly. The ancient Israelite and the Roman legionary were wont to gird their loins for effort, whilst the Indian and the Arabian of to-day still do the same.

But it may be asked, Why is it that all the women of the world as well as the men of tropical races should find such artificial support needed? The answer is that the human abdomen has certain structural disabilities and for obvious reasons. Man, as every morphologist knows, is built on the quadruped pattern. His abdominal organs and their encasement are similar to these of a horse or a dog. If his body was always horizontal, as it is in quadrupeds, then his abdominal organs would have in addition to their peritoneal slings the whole of the anterior walls of the abdomen as a hammock of support. But as man has chosen to become biped and erect this abdominal hammock is no longer available, and the organs, having to depend only on their peritoneal slings, which very easily stretch, tend to gravitate downwards and to unduly huddle against the lower front wall of the abdomen. It is true that "nature" has striven to aponeurotically strengthen this front wall, as, indeed, Sir Astley Cooper pointed out in his work on hernia, and this before Darwin wrote or the term evolution was coined. But up to the present this effort of nature in the roll of centuries is incomplete, and hence it is that the women of all races and the men of certain races have found for themselves the advantages of girding their loins and thereby artificially supporting the lower abdomen. It is scarcely necessary to point out why women need this girding more than men. The extra organ they possess, its situation in the lower abdomen, and its mutability in the exercise of its functions, all point to the need for quietude and steadiness. Nature has ordained that women should breathe pectorally so as not to perturb this abdominal organ, and any artificial support of the incompetent abdominal walls acts also in the direction that nature has indicated. Hence the use of the corset by women is in agreement with the dictates of nature and not contrary to them, as some critics would maintain.

One further point remains. What is the effect of compression over the lower abdomen upon the body generally: is it deleterious or beneficial? The answer to this has been most carefully investigated and given. In 1888 Professor Ray and Professor Adami delivered a conjoint address before the British Association on the "Physiological Bearing of Waist-belts and Stays," as the result of experiments they had made not only on humanity but also upon animals. Without going into the details (which are available in the volume of Proceedings), they found that a large amount of waste blood lay in the abdominal viscers, and that if these latter were gently compressed by a corset this

stagnant blood was driven into the general circulation and by being brought into service in the other parts of the body conduced to an increased muscular and mental activity. And they finally showed that all the physiological facts collected in their experiments explained "the beneficial and extensive use of some form or other of waist-belt by all nations who had passed beyond the stage of absolute barbarity." It will be observed that these gentlemen took no cognisance of the structural matters to which I have previously alluded, but simply investigated the result of abdominal compression as reacting on the body generally, and they found it beneficial. Moreover, they found that it increased muscular activity, a fact that disposes of the

contentions of the gymnastic critics. Having now given the reasons why corsets are needed, as well as the grounds on which they are beneficial, there remains to indicate what constitutes a proper corset from the medical as apart from the fashionable point of view. A proper corset should firmly support the loins and the lower abdomen, following in this respect the loin band or zone of the ancients. The waist should not be constricted nor should the stomach be unduly pressed upon, otherwise its churning of food in digestion will be checked. The top of the busk should not impinge on the lower end of the sternum, otherwise respiration will be interfered with. The corset may support the breasts if these are pendulous, otherwise it should fit but loosely to them. And it should fit closely and evenly along the back. If the textile portions of the corsets are thus rightly fitted, then certain supporting bones can be incorporated where needed, or even, as in the case of corsets that are worn for deformity, certain surgical adjuncts may be attached, and this without detriment to correctness of fit. If a medical man is called upon to give his opinion on a corset he should always see that he is able to pass his hand in front between the corset and the body down as far as the waist, thereby indicating that there is no undue pressure upon the parts traversed.

So much then for the rationale and rightness of corsets, but a further note or two may be of interest. When the long straight-fronted corsets of a few years since were in vogue I noted the common occurrence of what might be termed "corset dyspepsia," the stomach being so unduly pressed upon that it could not stir nor digest its contents. This malady did not attract medical attention, probably because with a change of the fashion it disappeared with its cause. Another interesting fact is that tightlacing is no longer the vogue. Statistics on this point were collected by the *Drapers' Record*, whose editor obtained returns from the principal manufacturers of corsets as to the waist measures demanded by the public. He commenced the inquiry in 1896, and has tabulated them up to a recent date. It is satisfactory to find that there has been a considerable increase in the waist measurement, although it is to be feared that this is rather due to changes in fashion than to medical warnings. Fashion has naturally controlled the shape of corsets, not only now, but in previous centuries. I am, Sir, yours faithfully,

Wimpole-street, W., Nov. 22nd, 1909.

HEATHER BIGG.

To the Editor of THE LANCET.

SIR,—It is refreshing to find the voice of common sense joined to the voice of authority in Mr. W. Arbuthnot Lane's paper on Civilisation and the Corset in your issue of Nov. 13th.

The corset of the present day—the "erect or American" corset—is the exact counterpart of the cast iron arrangement of our mothers. I tabulate the differences as follows:

Old Corset.

Back.—Rigid and straight; did not accommodate curves of spine; produced slouching.

Front.—Curved to form small Front.—Straight, simulates rectus

waist.

Height in front.—Extended to above level of nipples, compressing the whole of thorax and squeezing in lower ribs.

Depth in front.—Too short; compressed viscera of abdomen which protrude below the stays.

Front.—Straight, simulates rectus muscle.

Height in front.—Only extends to ensiform cartilage; leaves thorax free.

Depth in front.—Extends downwards to pubes; includes and supports abdominal viscera; shields abdomen

wards to pubes; includes and supports abdominal viscera; shields abdomen.

So well does an erect corset support the abdomen that for some time I have been in the habit of sending patients to the Potassium iodide is surely best given after a course of

corset-fitting room of good drapers whom years ago I should have sent to an instrument maker for abdominal belts.

For the benefit of the uninitiated I would remark that the corsets need to be properly adjusted. The laces should be well loosened, then the busks fastened, then the suspenders attached; and then the abdomen pressed upwards before the laces are tightened, and support is afforded to the figure.

I am, Sir, yours faithfully, (Mrs.) Latitia H. Andrew-Bird, L.R.C.P. Irel. Stoke Newington, Nov. 16th, 1939.

THE TREATMENT OF WHOOPING-COUGH IN GENERAL HOSPITALS.

To the Editor of THE LANCET.

SIR.-Mothers and school teachers do not appreciate the seriousness of whooping-cough, although it is a sad fact well known to medical officers of health. In my own area whilst the death-rate in 1907 from scarlet fever was only 0.15 per 1000 inhabitants that from whooping-cough was as much as 0.65 per 1000.

The following incident would appear to show that the seriousness and highly infective nature of whooping-cough are not appreciated also by the management of general hospitals. A mother recently informed my woman inspector that she was taking her little child to a large children's hospital in London to receive treatment weekly for whooping-cough. I was disinclined to believe this astounding statement, but direct inquiry proved that it was correct. Indeed, I was thus officially informed: "The hospital has a special department for this disease, which (department) is open twice a week." This is naturally with the approval of the medical committee, and I believe most of the children's hospitals have similar departments.

For my part I think this abominable practice should at once be stopped, as the number of children thereby infected must be considerable. Even this one case which has come to my knowledge may have done much harm in the weekly visits to hospital by infecting other children attending at the same time, and by infecting trains and trams and those using these public conveyances.

I am, Sir, yours faithfully

SIDNEY C. LAWRENCE, Medical Officer of Health. Town Hall, Edmonton, Nov. 16th, 1909.

THE TREATMENT OF CHRONIC ULCER OF THE LEG.

To the Editor of THE LANCET.

SIR,—Having read Mr. Willmott Evans's paper, "The Treatment of Chronic Ulcer of the Leg," in THE LANCET of Nov. 13th, 1909, I was very surprised to find that he thought more than 90 per cent. of chronic ulcers of the leg were syphilitic in origin. I should much doubt if this is the experience of most, and it is certainly not borne out by the results of the Wassermann reaction. I have the notes of 65 cases of chronic ulcer of the leg, both syphilitic and nonsyphilitic. From these only 15 gave a positive Wassermann. Of the 5000 cases described in the *Pructitioner* tested with the Wassermann reaction 70 per cent. of the cases of syphilis tested in the tertiary stage gave a positive reaction, many of these having no manifestation at the time; undoubtedly some of the cases were cured.

If over 90 per cent. of these cases of chronic ulcers were syphilitic a positive reaction should have been obtained in at least 40 out of the 65 cases. Too many cases are treated on the chance of their being syphilitic, without any thought being taken of the injurious effects of mercury, which one sees so commonly, especially in patients who have never had syphilis. It is no argument to say a case must be syphilitic because it improves on potassium iodide. In cases of chronic bronchitis there is probably no drug more useful. Further, iodides are not a specific against syphilis; they prevent fibrotic changes, especially in the tertiary lesions, but have absolutely no action on the syphilitic virus. Therefore, if an ulcer of the leg has been diagnosed as syphilitic mercury should be given at once, since it shows the activity of the syphilitic poison, and mercury is the only specific against it.

mercury, since it has the further action of eliminating the mercury which has accumulated in the system. In outpatient practice more harm than good is done by the injudicious use of fomentations. Patients allow the fomentation to get cold—the venous congestion is increased, the edges of the ulcer become sodden, ultimately necrose, and the ulcer is bigger than it was to start with.

The best method of cleaning an ulcer is to treat the leg as one would preliminary to an operation. Wash and shave all round the ulcer, scrape the raw surface, paint with pure carbolic, then well swab with absolute alcohol and lay on a piece of sterilised gauze upon which some Lassar's paste has been spread. A method of treatment not yet widely practised, but from the cases I have seen with the most extraordinary results, is the following. Scarlet red (Scharlachrot or Fettponceau R.), an aniline dye, is dissolved in chloroform and made into an 8 per cent. ointment with vaseline. A thin layer of the ointment is spread on a piece of calico and applied to the ulcer, but not allowed to remain for more than 24 hours. Boracic ointment is then applied for two days and the scarlet red repeated, and so on. In quite a short time the ulcer granulates up. Great care must be taken to clean the ulcer well before using the scarlet red. This method of treatment either brings about complete healing of the ulcer or makes the surface suitable for skin-I am, Sir, yours faithfully, grafting.

Harley-street, W., Nov. 23rd, 1909.

THE INFLUENCE OF DIET ON THE THYROID GLAND.

To the Editor of THE LANCET.

SIR,—The above subject has been brought somewhat prominently before us during recent years, and I should be glad to think that we now possess enough experimental evidence to guide us in the dietetic treatment of gout. Unfortunately we are still a long way from this goal, and although Dr. Chalmers Watson expresses the opinion that a protein diet causes the thyroid gland to enlarge and its microscopical appearances to change, I fear that many, if not most, of his fellow-workers will hesitate to venture so far ahead of established facts. Excessive meat-eating is a subject that has attracted a whole host of investigators, but I believe that none of them, with the exception of Dr. Watson, has been fortunate enough to produce the changes he describes. I myself carried out a series of experiments (an account of which was published in your journal a couple of years ago), but I had to cast my testimony on the side of the majority, for even after nearly two years of an exclusively protein diet the thyroids remained perfectly normal. I also made a comparative study of the glands in carnivorous and graminivorous birds. Here Nature herself performed the experiments and I merely recorded her results. But I found not only that the meat-eaters were not provided with larger and more active thyroids, but that, in some instances, they possessed glands which were strikingly inactive, much more inactive than in many purely vegetable-eaters.

Such facts as these are not, of course, easy to explain away. Yet they and the almost unanimous testimony of past observers must be disposed of before we can bring ourselves to accept that curious belief that our gouty patients will "strain" their thyroids if they eat meat in moderation, but will advantageously stimulate them if they consume it in unnatural excess.

I am. Sir, yours faithfully, Queen Anne-street, W., Nov. 22nd, 1909. DAVID FORSYTH.

DARWINISM AND MEDICINE.

To the Editor of THE LANCET.

SIR,-I think the time has arrived when a vigorous protest should be raised against the attitude of many scientists with regard to the abeyance of natural selection in civilised communities, and we must welcome Dr. Harry Campbell's timely letter on the subject. The idea that natural selection is in abeyance seems to be so congenial that it has gradually become more or less fully accepted without any real evidence whatever. To illustrate the position we may refer to the supposed degeneracy of the teeth. It has been observed that the teeth have become a positive menace in civilised communities, and the congenial explanation of this has

been that the skill of the modern dentist and the food of the civilised are of such a nature that those who have dental caries resulting from an hereditary predisposition to the disease are able to survive nearly or quite as well as those with sound teeth. This, it is contended, is why we find increasing numbers of decayed teeth among the civilised, whereas among the uncivilised the loss of even a few teeth would seriously handicap their possessors because these defects are not rectified, and the foods which perforce they must live upon demand a thoroughly efficient masticatory apparatus. When, however, we look into this argument we find it is quite hollow, for among those savages with the best teeth and having food which demands the most vigorous mastication there is practically no elimination because of carious teeth, as carious teeth practically do not exist among them. On the other hand, in civilised communities we find a large proportion of individuals with very bad teeth long before they reach maturity. It is now known that teeth do not decay except when the mouth is in an unhygienic state, and that this is brought about chiefly by the soft and sticky foods which lodge in the crevices of the teeth; and have we not learned in recent years that an unhygienic state of the mouth is the origin of a host of diseases which frequently lead to a fatal termination? This unhygienic state of the mouth often dates from infancy when on account of an erroneous theory a system of pap feeding (bread soaked in milk, milk puddings, &c.) is deliberately forced on children at a time when they are quite able and willing to eat bread or toast and butter, &c., and to drink what milk or water they require afterwards.

There is no precedent in the whole history of the evolution of man or animal for the soaking of bread or any other thing in milk. So throughout childhood the system is often more or less continued, the teeth become carious and the weakly children succumb, the disease which carries them off frequently having had its origin in the carious teeth. Are we, then, to believe that the mouth is not a common entrance portal of disease because the skill of the doctor and dentist prevents natural selection from having its way? Again, we know that many young women have a somewhat dilapidated dental armamentarium either with or without artificial substitutes. We know that this tends to give rise to ill-health-generally chronic. We know that a considerable proportion of them are unable to suckle their young as the result of their impaired health. finally, that among bottle-fed babies the mortality is much greater than among breast-fed babies. This chain of facts leads us to believe that there is greater mortality in children of mothers with bad teeth and unhygienic mouths than there is in the children of mothers with perfect teeth, and consequently there is an indirect elimination of those who are hereditarily predisposed to dental caries. It must, I think, be admitted that there is no evidence whatever that the teeth are degenerating because of the abeyance of natural selection. With regard to the idea that the diminution in the size of the civilised jaw has outrun the diminution in size or number of the teeth. Professor Arthur Thomson takes up a similar, if not identical, position to that which I myself took up in my book on "The Irregularities of the Teeth," and apparently believes that the crowding of the teeth is a "modificational" characteristic, for he indicates his belief in relation to this subject by saying that "far too little attention has been paid to what I call 'modificational' characteristics, which look as if they were inherited, but are not, being re-impressed or re-acquired in each successive generation.

I am, Sir, yours faithfully, ov. 22nd, 1909. J. SIM WALLACE. Wimpole-street, W., Nov. 22nd, 1909.

THE TREATMENT OF MORPHINISM.

To the Editor of THE LANCET.

SIR, -- In your issue of Oct. 16th Dr. Oscar Jennings of Paris criticises my method of treating morphinism by artificially inducing sleep during the painful withdrawal period. his point seems to be that the cultivation of the will is better accomplished by a painful than by a painless method when the latter is accompanied by hypnotic remedies. But my observations lead me to exactly the opposite conclusion. The long-drawn-out suffering caused by the ordinary gradual reduction method weakens not only the mind and body, bat

especially the will. Whatever tends to obliterate suffering conserves the strength of all the faculties of both mind and body, and thus lessens the liability of relapse after the patient leaves the sanatorium.

A few minutes after reading Dr. Jennings's criticism I chanced to meet a nurse who cared for her sister while she was under my treatment for morphinism. I told her of this criticism, and she reminded me of her own experience. Her sister had taken treatment for morphinism in two institutions before coming to me. In both places they used the usual painful reduction method, without much reliance upon drugs, and after each treatment she promptly relapsed. Since taking treatment with me she has not returned to the use of morphine, and long since resumed her usual work, maintaining the best of health. One of the glories of modern medicine is its conquest of pain. It is no mean achievement to keep a patient free from suffering while nature or art is busy restoring him to health. This is the object of my treatment of morphinism.

I am, Sir, yours faithfully,
Dorchester, Mass., U.S.A., Nov. 5th, 1909.
C. J. DOUGLAS.

HOSPITALS AND THE LONDON COUNTY COUNCIL: MEDICAL TREATMENT OF SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—There seems to be as great a diversity of interpretation of the arrangements entered into between various hospitals and the London County Council regarding the special medical treatment of children attending the Council schools, as there is difference of opinion in the prudence of such arrangements.

In the hope that the position taken up by the committee of the Central London Throat and Ear Hospital will commend itself to their subscribers, to the charitable public, and to the medical profession, I venture to give the resolution passed at our recent meeting, viz.:—

That the committee of the Central London Throat and Ear Ho-pital is willing, as hitherto, to receive those children of the London County Council schools who are suitable for hospital treatment so far as the capacity and resources of the hospital will allow.

It will be seen that we neither enter into financial contract nor give preferential treatment, our intention being to receive the children on their merits, not because they are children under the supervision of the L.C.C. but because they are children of the poor who have a claim on our sympathy and our assistance, the only passport needed being illness and the absence of means to pay for the adequate medical treatment of that illness.

I am, Sir, yours faithfully,

RICHARD KERSHAW.

Central London Throat and Ear Hospital, Grays Inn-road, Nov. 17th, 1909.

THE EYESIGHT OF SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—May I suggest that the medical officers who are examining school children in the elementary schools should inquire what kind of artificial illumination is provided in the school by which the children have to perform their writing and reading lessons during the dark foggy days so prevalent at this season of the year? I understand that in some schools there is quite inadequate illumination, the ordinary old-fashioned gas-jet being used without applying the modern methods of illumination, even by those boroughs which have electricity works of their own. Examination of the children's eyes at this time of the year could conceivably show the effects of eyestrain due to this cause and give misleading results for tabulating purposes.

I am. Sir, yours faithfully,

London, Nov. 17th, 1909.

A PARENT.

LITERARY INTELLIGENCE.—Messrs. Baillière, Tindall, and Cox will shortly publish a handbook by Captain E. Blake Knox, R.A.M.C., M.D., D.P.H., entitled "Aids to Microscopic Diagnosis (Bacterial and Parasitic Disease)," which will present a concise account of clinical laboratory technique.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Institute of Sanitary Engineers.

Mr. J. D. Watson, engineer to the Birmingham Drainage Board, delivered his presidential address to the Birmingham and Midland section on Nov. 16th. The subject was "The Disposal of Sewage at a Country House." He directed attention to the need of making owners and occupiers realise the need for improvement and for efficient methods of dealing with sewage. Many beautiful streams were polluted because no attempt at purification of sewage was made. A natural method of purification was the best, and that might be done by land irrigation or by artificial means or bacteria beds according to circumstances. The quality and suitability of land were of great importance, some soils being capable of purifying more than 30,000 gallons of sewage per acre per day, and other soils not a tenth of that amount. Assuming a typical country house inhabited by ten people, with a total volume of sewage of about 300 gallons per day, he recommended the establishment of a bacterial plant on the percolation system.

Parents' National Educational Union.

The annual conference was held in Birmingham from Nov. 15th to 19th. Much interest has been taken in its proceedings. On the first day a large meeting, presided over by Lord Lytton, was held in the great hall of the new University buildings, and an address was given by Sir Oliver Lodge. Among other notable addresses were those by the Bishop of Birmingham on "Shall we send our Sons to the University?"; by Canon J. H. B. Masterman on "The Education of the Imagination"; by Sir Martin Conway on "How to Interest Young People in Art"; and by Dr. Helen Webb on "Environment in Relation to Nervous Stability."

Death of Alderman Alfred Barratt, M.R.C.S. Eng., L.R.C.P. Edin.

I record with regret the death of Alderman Barratt on Nov. 18th at the age of 81 years. Mr. Barratt was trained at Queen's College, Birmingham, and qualified in 1855. For about 30 years he worked a large general practice in a thickly populated artisan district. In 1870 he was elected to the town council and joined the small band of publicspirited men who, under the leadership of Mr. Joseph Chamberlain and Mr. Jesse Collings, strove successfully to reform the constitution of the council and its methods of working, so bringing about a vast improvement in the town. His professional knowledge was of great service to the health committee, drainage board, and estates committee, of which he was a member. He was also a member of the committee which carried out the great improvement scheme when a number of old slums were cleared away to make room for handsome business streets. For 20 years he was a member of the board of guardians, of which he was chairman in 1885. At the time of his death he was a member of the board of overseers. He lived a strenuous life, and was a good example of a public man actuated by the highest motives.

Royal Leamington Spa.

The town council has decided to enter upon a scheme to reorganise the baths and make them better known. A weak saline water is to be supplied in addition to the strong saline water now in use; a medical pamphlet will be drawn up; a sum not exceeding £500 will be spent on advertising; and an annexe to the pump room will be provided.

Nuneaton General Hospital.

At the annual meeting of the supporters of this hospital a motion was proposed to rescind the rule restricting the hospital medical staff to six, and substituting a rule that all the duly qualified medical men in the town after 12 months' residence should be members of the staff, if they desired, on application to the management committee. It was pointed out toat working men contended that patients when they go into hospital should have the privilege of being attended by their own medical men. After a long discussion the motion was lost by 60 votes to 48.

Nov. 23rd.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Overcrowding of Bridgend Workhouse.

THE population of the Bridgend and Cowbridge Union increased during the decade ending 1901 by 16,000 persons, and it is probable that a proportionate increase has been going on in the past eight years, so that it is not at all surprising to find that the accommodation provided in the union workhouse has frequently been over-taxed. Alterations to the infirmary have resulted in this portion of the institution being placed in a very satisfactory condition, but according to a report recently presented by Mr. L. M. Shadwell other parts of the workhouse are very unsatis-Some of the female dormitories have been given factory. over to the use of the men, so that the women and children are in very restricted quarters, as many as 35 of them being in a room in which only 18 should be accommodated. Provision for escape in case of fire appears to be very inadequate on both sides of the house and in other ways structural alterations are necessary. It should, in fairness to the board of guardians, be stated that, following the example of similar bodies elsewhere, it has been considered only prudent to await the recommendations of the Poor-law Commission before embarking upon an extensive building scheme, and it now appears to be not unlikely that with an extended scheme of classification and a wider area of administration the necessity for the enlargement of existing Poor-law institutions may be met by utilising unoccupied portions of similar institutions in other parts of the county.

Infantile Mortality in Nowport.

The infantile mortality rate—135 per 1000 births—recorded in Newport for 1908 compares very favourably with that of 10 years ago, when it was 179 per 1000. This very considerable reduction is no doubt due in great part to the efforts which have been made by the sanitary committee of the corporation to improve the surroundings of the working-class population of the town. There are, however, possibilities of still further improvement, and in his recently issued annual report the medical officer of health, Dr. J. Howard-Jones, refers to the large number of preventable infantile deaths as an indication of the necessity for some radical changes in the education of girls so that they may be better prepared for their life work as wives and mothers of the nation. He further urges the necessity for the cooperation of the public with the sanitary authority in the endeavour to reduce the large amount of infantile sickness and mortality. With the object of securing this coöperation a scheme has been inaugurated in Newport for the purpose of establishing a school for mothers somewhat on the lines of that which Dr. J F. J. Sykes has instituted in The objects of the school are to promote infant St. Pancras. and domestic hygiene and the natural feeding of infants, to afford assistance to mothers in necessitous cases where they appear to be in want of the nourishment required for the continuance of breast-feeding, and to advise mothers generally upon the care of their children as regards feeding and clothing. Milk is supplied daily to mothers during the first month after their confinement on condition that they drink it themselves and continue to nurse their infants, and necessitous mothers are supplied with dinners at a nominal charge. Newport school appears to have been formed upon sound lines and will, no doubt, meet with the success which has attended similar undertakings elsewhere.

Monmouthshire Water-supply.

The scarcity of water in certain parts of the Monmouthshire colliery districts has been frequently commented upon, and the increase in the population of both the eastern and western valleys makes it more and more imperative that an adequate supply should be provided. The very laudable effort which the county council made two years ago to obtain water from the Brecknockshire hills was unfortunately unsuccessful, but it is satisfactory to find that two urban district councils, those of Abertillery and Abercarn, have decided to promote a Bill in the next session of Parliament for the purpose of forming a joint water board. The scheme of the councils includes the impounding of water in Brecknockshire and conveying it to the western valleys. It is anticipated that there will be a sufficient supply not only for the two districts named but for several of those adjoining.

Nov. 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Appointments at the Royal Infirmary, Edinburgh.

THE managers of the Edinburgh Royal Infirmary at their meeting on Nov. 15th appointed Mr. Henry Wade, F.R.C.S. Edin., an assistant surgeon to the infirmary, and at the same time appointed Dr. James Miller, formerly of the University of Birmingham, an assistant pathologist in the pathological department of the infirmary. There were several candidates for both posts, but the appointments fell to the men who were generally expected to secure them.

Edinburgh School Board Appointments.

After a good deal of trouble the Edinburgh School Board has decided to appoint two medical officers at a salary of £250 a year each. It originally proposed to appoint a man at £250 and a woman at £200. The women at once took steps to dissuade any of their number applying for the post, and it is thought that two men may be selected. For the kind of work there is no doubt as to the suitability of women, and when the School Board recovers from its annoyance at being checkmated the members will realise that the position the women take up is equal pay for the same kind of work for both sexes, and that this is the fair position.

Improvement of Medical Education in Edinburgh.

For some days past communications and letters have been appearing in the Scotsman dealing with defects and proposed improvements in medical education in Edinburgh. These have evidently been largely inspired by the report which has been issued from the Edinburgh Pathological Club on the condition of the school. At an early date the directions in which improvement is most necessary may be dealt with. Meanwhile the strong impression is that it will be exceedingly difficult to induce the professoriate to move from its present position, while those who see the need of change are prone to ask too much and to mix up issues.

Appointment of an Edinburgh Anatomist to a London Chair.

Dr. David Waterston, at present lecturer in anatomy to the University of Edinburgh, has received the appointment of Professor of Anatomy in King's College, London. Dr. Waterston is a son of the Rev. Richard Waterston, and is an M.D. of Edinburgh, receiving a gold medal for his thesis. After the death of Professor Cunningham, Dr. Waterston was acting professor of anatomy at the University, and previously to this he was assistant to both Professor Cunningham and Sir William Turner. He is a Fellow of the Royal Society of Edinburgh and a Vice-President of the Royal Physical Society. Dr. Waterston commands the medical unit of the Officers' Training Corps in the University, and takes an active interest in matters Territorial. He has contributed extensively to literature and has edited a popular Stereoscopical Atlas of Anatomy.

Nov. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Temperance Crusade.

DRINK has confessedly always proved one of the most dangerous enemies of the Hibernian Celt, whose sociability and excitability made him so much more prone to the ready display of its most mischievous effects. One of the good results of the recent temperance movement throughout this country has been in the extension of means for the provision of food for persons attending fairs and markets. At a recent meeting in Athlone it was decided to purchase a coffee van which is to be used on these occasions; the experiment has already been made in other districts with ment has already been made to serve a twofold object. The detestable product known as "fair-day whisky" is struck at directly, while a crying wan of those who have to attend in the grey morning hours to the urgent and trying transactions of fairs is efficiently supplied. Very moderate prices are charged for the refreshment thus supplied, while it is pointed out that as the benefit conferred by such facilities will be reaped by the great majority of the public there is no reason why these undertakings should not be made self-supporting. In former

years the herd, cattle drover, and grazier always started for the fair—at which the most important of the items of their annual business was transacted—before dawn, and on a perfectly empty stomach. It was unmanly to do otherwise, or even suggest a change of custom. So absorbing was the enthusiasm for business that no idea of refreshment was entertained till the cattle were delivered and paid for. And then—the reward for the ordeal was furnished by the fresh whisky, specially prepared for the occasion by distillation from treacle or potatoes. It had a "grip" which was appreciated and it went "straight to the head," from which it banished all thought of care and consequences. Alcohol is receiving the fullest attention in Ireland, where so large a proportion of the annual expenditure is thereunto devoted.

The Tuberoulosis (Ireland) Act, 1908: Rejection by the Athy Board of Guardians.

The question of the adoption of the Tuberculosis (Ireland) Act, 1908, was brought before the Athy board of guardians at last week's meeting, and Surgeon-Colonel Edgar Flinn, medical inspector to the Local Government Board, attended for the purpose of furnishing the debaters with expert advice. After the adoption of the Act had been duly moved and seconded, Colonel Flinn pointed out to the meeting that the opposition to the adoption of the compulsory notification of phthisis was merely a slightly modified replica of the hostile demonstration elicited by the passing of the Compulsory Notification of Diseases Act nearly half a century ago—a measure which proved itself in practice to be both wise and beneficent. A guardian then pointed out that the adoption of Part I., or the compulsory part, would be of little practical value unless Parts II. and III. were put into operation, which conferred the power to erect sanatoriums. A division was then taken, with the result that—by a majority of 15 votes to 8 the meeting refused the adoption of the Act.

The Ulster Medical Society.

The an ual dinner of the Ulster Medical Society was held in the Medical Institute, Belfast, on the evening of Nov. 18th, when Dr. J. J. Austin, the President, occupied the chair. The toasts were as follows: "The King," given by the chairman, and also "The Lord Lieutenant and Prosperity to Ireland," to which Sir W. Whitla replied. Mr. R. J. Johnstone proposed "The Guests," to which Dr. T. H. Moorhead (Cootehill), President of the Ulster Branch of the British Medical Association, Mr. R. M. Jonas (headmaster of the Academical Institution), Mr. R. J. MacMordie, and Mr. H. Garrett replied. Sir John Byers proposed the toast of "The President of the Ulster Medical Society," to which Dr. Austin, who was very warmly received, replied. During the proceedings excellent songs and recitations contributed to the enjoyment of the evening.

The Belfast Medical Students' Association.

The inaugural meeting of the Belfast Medical Students' Association was held in the McMordie Hall. Students' Union, Queen's University of Belfast, on Nov. 19th. An introductory address on Post-Graduate Study having been given by the President, Dr. P. T. Crymble, Dr. G. A. Gibson (Edinburgh) delivered a lecture on "Modern University Ideals." At its conclusion the lecturer was accorded a vote of thanks.

Queen's University of Belfast.

Mr. R. M. Beath has been unanimously elected President of the Students' Representative Council, and will, in consequence, be entitled to a seat on the Senate of the University for the coming year. Nov. 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Extraction of a Revolver Bullet Lying Loose in the Spinal Canal.

AT a meeting of the Academy of Medicine held on Nov. 2nd M. Tuffler described the case of a woman, aged 56 years, who was shot with a pistol in the abdomen and several weeks afterwards was seized with pain in the left thigh. Radiography showed the bullet lodged in the spinal column, but on operating M. Tuffier failed to extract it, notwithstanding the precision with which it had been located, and a second examination with the X rays showed that it was loose in the first and the last lumbar vertebræ. It was extracted in a second operation, during which the woman was in a kneeling position, and all the nervous troubles then disappeared.

Vaso-Vesiculectomy for Tuberculous Disease.

At a meeting of the Surgical Society held on Nov. 3rd M. Marion reported two cases of vaso-vesiculectomy under the care of M. Baudet. The first patient was a man, 32 years of age, who was admitted to the Hopital Lariboisière suffering from a swelling of the right side of the scrotum, an abscess opening below and behind, and a fistula. Rectal examination showed that the right vesicula seminalis was enlarged. An operation was performed on May 27th. An inguino-scrotal incision having been made, the epididymis was removed, and the whole anterior wall of the inguinal canal was incised down to the peritoneum which was turned inwards. The vas deferens was then isolated and followed to the vesicula seminalis which was removed. In the second patient, who had been kept in sight since the operation and had been seen 11 years afterwards, both vesiculæ seminales were removed, but on the left side the testicle was healthy. It must, therefore, be admitted that tuberculosis commenced in certain cases by the vesicula seminalis. Such operations on the reproductive organs were difficult in the performance and the results were not very striking. According to the statistics of M. Baudet and M. Kindindjy death by septicæmia occurred in only one case out of 57. Death might occur at a late stage by extension of the pulmonary lesions. The urinary fistulæ generally closed at the end of three months. M. Marion said that operation was obligatory in presence of urinary fistulæ, rectal tenesmus, and cystalgia, but that it was optional when the vesiculæ seminales were enlarged without being painful and did not undergo retrocession after an operation on the epididymis.

Treatment of Empyema.

M. Pailloz has laid before the French Society of Military Medicine the results of 28 pleurotomies which he performed at the hospital of Saint-Miniel on men suffering from purulent pleurisy. Among these patients there were 24 recoveries and 4 deaths. M. Pailloz remarked on the necessity of making an early diagnosis. For this purpose exploratory punctures must be promptly undertaken, not with a Pravaz syringe, which was quite inadequate, but with Potain's trocar. An operation should be performed as soon as puncture revealed the presence of pus in the pleura. The best operation, and the only one which provided sufficiently for drainage, was pleurotomy with resection of a rib. Disinfection of the skin should be carefully attended to in the subsequent dressings, so as to avoid infection of the lips of the wound which might seriously retard cicatrisation. The amount of the patients' food soon required to be increased. M. Pailloz used chloroform as the general anæsthetic in all cases. Treated on the principles above described an empyema would terminate in recovery after about 45 days.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Question of Gratuitous Attendance on Medical Practitioners and Their Families.

THE committee of the Prussian Medical Chambers, consisting of the official representatives of the medical profession, has prepared a draft code of ethics, in one paragraph of which it is said that a medical man should attend his professional brethren and their families free The editor of the Deutsche Medizinische Wochenschrift Professor Schwalbe, has commented adversely on the proposal of the committee as being no longer in accordance with the general circumstances of the profession. He explains that in former times, when the number of medical men was comparatively small even in important towns, the practitioners in each district knew one another and had opportunities of meeting in social intercourse. It was under these conditions that the custom of gratuitous attendance on professional brethren grew up and the custom was a good one, but at the present day the number of practitioners is so great that many of those in the larger towns have never been introcerebro spinal fluid and capable of travelling between the duced to one another. It must also be remembered that the

number of specialists was formerly very insignificant, and practitioners used to attend cases of every kind: when one of them or a member of his family became ill he called in a medical neighbour, to whom he rendered a similar service when the occasion arose. Nowadays, a medical man wishes his wife to be attended at her confinement by an obstetric specialist and the illnesses of his children to be treated by a specialist for children's diseases. general practitioner, moreover, expects this attendance to be given free of charge, although he is obviously not in a position to requite the specialist by rendering him professional services in return. It is also assumed that this obligation on the part of the consulting physicians and surgeons includes not only their professional brethren living in the same town but those in any part of Germany and abroad. It is true that the majority of medical men instead of paying fees are in the habit of either giving pictures, ornamental objects, trinkets, or other presents to their medical attendant or else of paying a certain sum to charitable institutions in which he may be interested, but on the whole the consulting physician or surgeon not only does not receive adequate remuneration for his work, but he may even incur expenses out of pocket. A physician carrying on a large practice in Berlin told Professor Schwalbe that he is consulted nearly every day, and sometimes three or four times a day, by medical men or members of their families during his consulting hours, and that he has been asked to see the wife of a medical man in a provincial town, which he did, thereby losing the whole day without being even repaid his travelling expenses. The system, in fact, involves disadvantages not only for the consultant but also for the practitioner who happens to be in need of advice or attendance, because the latter, through unwillingness to accept services which in some degree partake of the nature of charity, will certainly hesitate to consult a specialist even when necessary. Unpleasantness has occasionally arisen through the disinclination of certain practitioners to undertake the treatment of professional colleagues or members of their families. Some years ago a medical man in Berlin complained in the columns of a professional journal that when his mother, who lived in his house, had become very ill at night during his absence several medical men of the neighbourhood made various excuses for not coming to her assistance. Professor Schwalbe is therefore of opinion that it is not advisable to stipulate, by a paragraph in the code of medical ethics, that medical men and their families are to be exempted from paying fees, but thinks that this question should be left to a free agreement between both parties in each individual

Pregnancy and Diabetes.

At a recent meeting of the Berlin Medical Society Dr. Neumann read a paper on Pregnancy occurring in Diabetic Women. He said that three conditions had to be considered -namely (1) whether the woman was healthy previously to conception and became diabetic afterwards; (2) whether she was healthy at the time of marriage but became diabetic before conception; and (3) whether she was diabetic at the time of her marriage. The mortality of pregnant diabetic women was very high—about 50 per cent. -the principal causes of death being either coma or tuberculosis. The fætal mortality was about 51 per cent., while of the children born at full time 50 per cent. died within the first month. It has therefore been recommended that premature labour should be induced in diabetic women. Dr. Neumann, however, has now found in six cases that adherence to a strict antidiabetic diet made this procedure unnecessary, that normal delivery took place, and that the children were strong and healthy without showing signs of diabetes in the first years of life. The fact that he had six cases of pregnant diabetic women under his care was somewhat remarkable as sterility was rather frequent in diabetic women. Notwithstanding his good results he recommended that diabetic women should not marry and that when married they should refrain from conception. In the event of pregnancy occurring a strict antidiabetic diet was necessary from the beginning. Premature labour, he thought, should not be induced merely because a woman suffered from diabetes.

Dermatitis caused by Satin-wood.

At a recent meeting of the Hufeland Society Dr. Siegheim gave an account of an outbreak of dermatitis caused by satin-wood. The patients were 25 cabinet-makers employed

in a workshop where this wood was used, and the outbreak resembled those previously chronicled. The dermatitis was very like that caused by plants of the genus primula, being spread over the face and the arms, but not affecting the conjunctiva, the mouth, or the penis. In one case there were cedema and a nodular exanthem of the tnighs and feet. Anorexia and headache were present, but there was neither pyrexia nor albuminuria. The exanthem disappeared when the patient left the shop for a few days, but a relapse occurred in one instance. The treatment consisted in the application of oxide of zinc. Dr. Siegheim was of opinion that the dermatitis was caused by an alkaloid contained in the wood. A similar outbreak of dermatitis was lately observed in Breslau, where it was caused by foreign oak-wood. Covering the hands by chirosoter was a good prophylactic. Professor Jones expressed his agreement with the view that the wood contained an alkaloid; on the surface of the wood there were minute crystals which might easily be spread about. Dr. Somerfeld mentioned that the same disease was caused by Japanese lac. 1

Nov. 22nd.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

" Our Gideon Grays."

Dr. John Brown's "Horae Subsecivae" contains a memorable plea for the "country doctor" as he lived, laboured, and "entered into rest" during last century—a plea which took inspiration and title from the "village practitioner" as typified in Scott's "Surgeon's Daughter," from whom, says Sir Walter, "Scotland reaps more benefit and to whom she is perhaps more ungrateful than to any other class of men, excepting her schoolmasters." Italy, as in the day now passing, has her "Gideon Grays," has "medici condotti," to wit, or communal practitioners, who keep her rural population in health and confidence on a stipend which their British counterpart of "sixty years since" would not have found a living wage. These men, their "rugged conditions" notwithstanding, are, as a rule, so devoted to their profession on its scientific side that, wherever they have the chance, they give up their brief holiday to the post-graduate courses now open to them in nearly all the great clinical centres of Italy. In Milan, for instance, some 50 of them completed on Saturday last their third "corso di perfezionamento," and before separating for their remote spheres of duty met in fraternal symposium at a well-known restaurant of the city. Their conversation turned naturally on the life they led, its conditions and its prospects, and finally resolved itself into a discussion motivée by a cordial telegram received from Dr. Brunelli, Member of Parliament for Lugo and President of the "Associazione dei Medici Condotti." "From the university," said one of the interlocutors, "we are told off into secluded mountain districts, often to be the sport of the syndic, the communal clerk, and the priest whose interests are seldom ours and whose caprices we have to 'grin and bear.'" Evidence in this sense was multiplied by other speakers, one of whom summed up the "situation" as follows: "Orario (table of professional hours) covering all the day and most part of the night; shortage, often absolute want, of the medicaments and appliances necessary for successful practice; salary 2000 lire (£80) & year." Hard lines these; and after 25 years of work on such terms, during which the doctor makes an annual pay ment of 130 lire (£5 4s. 2d.) to the Cassa Pensione, he may expect a retiring allowance of 500 lire (£20) per annum. The symposium came finally to an "order of the day." voted unanimously, in which the Government were petitioned for legislative interference in behalf of the "medici condotti, with a view to the redress of existing grievances and the enactment of conditions commensurate not only with the just claims of the petitioners but with the public interests the said petitioners are called upon to serve.

The Argentine Republic and its International Congress and Exhibition of Hygiene.

In the summer of 1910 the Argentine Republic—wellnigh Italian in its civilisation and citizenship—celebrates the first centenary of its independence, and prominent among the

incidents of the commemoration will be an international congress and an international exhibition of hygiene. The congress and exhibition alike will be inaugurated on May 25th at Buenos Ayres, and the exhibition will remain open till Nov. 25th of the same year. Under 14 different heads it will comprise specimens of every object, appliance, and practical method known to sanitation in its widest sense, and already more than one of the continental powers are taking steps to be represented in the various sections. Exhibits will be accepted up to March 31st and will be exempt from all import dues whatever, except in the case of their finding purchasers at the close of the exhibition. The navigation companies will (it is understood) concede transport of goods as well as of passengers at reduced rates, precise particulars as to which will in due course be ascertained at the Consulates and Vice-Consulates of the Argentine domiciled in Italy. Meanwhile, information as to terms of admission and other details of interest to intending exhibitors can now be had on application at No. 15, Via Monte della Pietà, Milan, the seat of the Commissione Esecutiva del Comitato per le Esposizioni all' Estero.

Nov. 14th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Typhoid Fever.

In some of the local newspapers reports have appeared of the outbreak of the epidemic of typhoid fever in different quarters of the metropolis. The cause is attributed to bad drinking water. I myself have seen in the course of the last few months quite an unusually large proportion of typhoid fever cases at Haskeuy and Balat, two districts on the Golden Horn. Numerous people in Constantinople firmly believe that all the sources of water-supply here are contaminated and absolutely dangerous to be used for drinking purposes. Even the famous Sultan souyon (Sultan's water) got from the street fountains, which has, up to now, enjoyed the reputation of being perfectly pure, has now been condemned by a large section of the population as being also polluted. Although many of the popular fears are groundless, there can be no doubt that many of the water sources of the capital are anything but pure. This is the opinion of the special Commission that was appointed some time ago to examine them. The so-called Derkos water which supplies a large section of the city, and which many use unboiled and unfiltered, is certainly impure.

Malarial Fever.

Another epidemic—namely, that of malarial fever—is raging in the vilayet of Houdavendighiar. It is especially severe in Nicæa, where (so says the Osmanischer Lloyd) there is no house without a sufferer from the disease, and where the medical man himself is laid up. Since there is no druggist or chemist in that place people are forced to buy quinine from the bacal (grocer). It has been found that this drug is not of the necessary quality, with the result that the disease still continues its ravages. The medical man says that he has already several times asked the municipality of the town to take the necessary measures of prevention, but in vain. He was always answered that for the successful combating of the epidemic the sum of £500 would be required, which was not available. In Nicea as many as 60 persons have died from malaria in the course of the last few weeks. The opinion is expressed that the cause of the epidemic lies in the swamps of the district. The canal of Ghemlik, which unites the Lake of Nicæa with the Marmora Sea, has not been for a long time past in good working order, and the accumulations in the swamps have consequently not found the necessary exit. A large part of the population of Nicæa have expressed the to undertake the work of clearing the canal and the swamps. The inhabitants of Ghemlik, however, energetically object to this undertaking, as they fear that the clearing of the place will result in an inundation. dilemma is rather a difficult one, and the authorities are undecided what to do.

The Hospital of Gouréba.

Hamada Pasha, the Minister of Evkaf (religious property)

has inspected the Gouréba hospital of the metropolis and found it in a most deplorable condition. Complaints of the bad management of this institution have been very loud for a long time past. A special commission has been formed, consisting of the surgeon Djemil Bey, Mustafa Bey, the Director of the Faculty of Medicine, and Dr. Nizameddine Bey, to investigate the matter. This commission has now submitted a report which completely condemns the administration of the hospital. Gouréba is one of the most important national charitable institutions of Constantinople, containing as it does 300 beds. The management seems to have been utterly neglected. Typhoid fever cases were confined in one room in very large numbers. Disinfection was hardly ever undertaken, and when undertaken it was done in a superficial, casual manner. The most primitive hygienic measures were neglected. An idea of the great mortality that prevailed at Gouréba can be formed from the large sum spent for shroudclothes. It has been proposed that the direction of the hospital should be intrusted to Dr. Nedimeddin Arif Bey, who has studied in Paris and Berlin, and who lived in exile during the old régime.

Nov. 18th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Peliagru Board of Investigation.

The increasing prevalence of pellagra in the Southern States has led the Government to appoint a board of investigation as to its cause and the preventive measures necessary for its arrest. This board is empowered to visit the localities where the disease is most prevalent, to make such inquiries and investigations as may be found necessary, and to confer and coöperate with local health authorities in instituting the measures found to be essential to the extermination of the disease. The board consists of medical officers of the Public Health Service of large experience in the investigation of pestilential diseases, and experts in laboratory experimental work.

Accidents from Automobiles.

The National Highways Protective Society has published a list of the killed and injured in New York during the menth of October by automobiles. The total number killed was 22 and injured 33. Within the traffic lines, where the police are stationed at intervals, there are no accidents, but in the suburbs, where there is no such protection, the accidents chiefly occur. The society states that the average rate of speed in the streets is 20 per cent. higher than it was and is steadily increasing; the trouble is with the drivers. Any man who sends \$2 to the Secretary of State and asserts that he has had a certain amount of experience may have a licence to drive; the result is that even exconvicts, whose photographs are in the Rogues' Gallery, are driving some of the taxicabs. The society has decided to endeavour to secure legislation creating a Highway Commission with power to issue licences to chaufteurs and to regulate the operation of automobiles in cities and villages.

The Rockefeller Commission for the Eradication of the Hookworm Disease of the Southern States.

The creation of this Commission and its endowment with \$1,000,000 is an interesting if not a unique instance of a great work of public beneficence by private wealth. Mr. J. D. Rockefeller, recently organised a Commission of expert medical scientists, of which Professor Welch of Johns Hopkins University is the president, and addressed to it a communication, saying: "For many months my representatives have been inquiring into the nature and prevalence of hook-worm disease and considering plans for mitigating its evils. I have delayed action in the matter only until the facts as to the extent of the disease could be verified and the effectiveness of its cure and prevention demonstrated. If you deem it wise to undertake the Commission I shall be glad to be permitted to work with you to that end, and you may call upon me from time to time for such sums as may be needed during the next five years for carrying on an aggressive campaign, up to a total \$1,000,000." In accepting membership of the Commission the members replied as follows: "Your generous offer has our

heartiest approbation and we accept your invitation to administer this trust with a keen appreciation of the opportunity that you give us to do a great public good. The hookworm parasites often so lower the vitality of those who are affected as to retard their physical and mental development, render them more susceptible to other diseases, make labour less efficient, and in the sections where the malady is most prevalent greatly increase the death-rate from consumption, pneumonia, typhoid fever, and malaria. The disease can be easily recognised, readily and effectively treated and by simple and proper sanitary precautions successfully prevented." It may be interesting to notice in this connexion that there has long been a class of inhabitants of the Southern States which has been known as the "poor whites." They have been characterised by their listless habits and extreme poverty and apparent want of interest in business of every kind. In 1902 Dr. Charles W. Stiles, chief of the division of zoology in the hygienic laboratory, announced that the "poor whites" were not wilful degenerates but helpless invalids, and that the cause of their condition was the uncinaria or "hookworm," an intestinal parasite probably brought from Africa by slaves many generations ago. Dr. Stiles's investigations showed that this disease was extremely common among the poorer and unhygienic classes, and he was led to estimate the number of victims of this parasite at 2,000,000 at least, and probably a far greater number of sufferers actually exist. The discovery of this disease and its cause excited no other public comment than that it was a remarkable explanation of the peculiar habits of laziness of a class of people in which no one was especially interested. A Southern newspaper says: "The ridicule which Dr. Stiles's discoveries received at the outset now seems itself ridiculous. The idea of a germ of laziness could not at first be assimilated by the public mind. The hookworm was soon a subject of popular jest, and its finder became the butt of many dull jokes. But public disbelief and contempt only spurred Dr. Stiles to repeat his experiments and to stand on his discoveries. When William H. Welch and Simon Flexner, America's greatest pathologists, lend their support to a campaign against hookworm popular support must follow. Their approval is the seal of scientific authority.

Vital Statistics in the United States in 1908.

The chief statistician of the Bureau of Vital Statistics, Dr. Cressy L. Wilbur, states that the civilised world has reached an era of low mortality. The death-rate in the registration area in 1908 was 15·3 per 1000 population. This rate is the lowest that ever occurred in the United States. In the rural portion of the registration States the death-rate is even lower, being only 14 per 1000, while that of the urban population was 16·5 per 1000, the latter including all cities having a population of over 8000 in 1900. The year 1908 must be considered as one of extremely low mortality throughout the United States, but while it was marked by a general absence of severe epidemics there was unusual mortality from other causes.

Importance of Government Control of the Sale of Vaccine Virus.

The sale of vaccine virus by private pharmaceutical firms requires a Federal licence. Recently the Public Health Service discovered that a firm which makes vaccine virus one of its products had prepared a large amount of virus which was demonstrated to be contaminated. On reporting this fact to the Government office, the license of the firm was suspended until it had withdrawn all of the contaminated virus from the market. The company then withdrew the condemned product from the market and destroyed it, the value of the amount destroyed being estimated at more than \$14,000. The firm then presented a bill to the Government for the amount of loss, which was refused.

Concentration of Offices of Physicians.

For several years the profession of New York has had a central building devoted exclusively to the offices of medical men and called "The Sydenham." The movement was at first received with marked disfavour, but has now become decidedly popular. In Philadelphia the profession is about to erect a building for this purpose at a cost of \$500,000 and with facilities for 200 offices.

Nov. 6th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending Oct. 2nd showed 3460 deaths, compared with 2595 in the week preceding. Bombay Presidency reports 911, Madas 141, Bengal 31, the United Provinces 236, the Punjab 193, Burma 30, Central Provinces 1063, Mysore State 248, Central India 305, and Rajputana 274. For the week ending Oct. 16th the returns show 4175 deaths, compared with 4123 in the week preceding. Bombay Presidency reports 924, Madras 74, Bengal 61, the United Provinces 367, the Punjab 321, Burma 25, the Central Provinces 1304, Mysore State 216, Central India 430, and Rajputana 421. Stringent sanitary measures and inoculation against plague are reported in progress in Mysore city in view of the large gathering of people expected there for the Dussean festivities this month, which include the holding of the annual agricultural and industrial exhibition, and also in view of the Viceroy's visit to the city towards the end of The health of Mysore is not satisfactory as next month. plague is epidemic, and about 10,000 persons in the vicinity of the palaces have been inoculated. In Bangalore the plague inoculations commenced just two years ago, and as a result of house-to-house inoculation the aggregate to-day reaches 70,000 inoculated and re-inoculated out of a population of 90,000. The resulting immunity has been very marked, in that only about 1 person per 1000 has been attacked by plague.

Vaccination in Benyal.

A series of interesting experiments have been carried out during the past year in various districts of Bengal Presidency, chiefly with glycerinated lymph manufactured in the Central Animal Vaccination Depot, Calcutta. The results achieved appear so satisfactory that the civil surgeons of Howah. Gya, and Midnapore have recommended the substitution of this lymph for the lanoline vaccination paste at present being used. The chief drawback to its use, however, appears to be that it is liable to deteriorate through heat and does not retain its efficiency so long as does the lanoline It also requires careful handling by the vacci-The Sanitary Commissioner intends to give this paste. lymph a further trial exclusively in two or three selected districts, and if successful the question of its general introduction will be considered. A satisfactory feature during the year has been the appointment of a special inspector of vaccination at Orissa. It has given considerable impetus to vaccination in the districts of Puri and Cuttack. This specially trained officer by tact and energy succeeded in overcoming the opposition to vaccination generally shown by villagers, and induced the natives of tracts affected with small-pox and other districts where vaccination had always been resisted to come up for vaccination. By these means an epidemic was cut short at Puri and the mortality greatly reduced. Another result attributed to the same agency was the marked increase in the number of infants vaccinated in Cuttack and Puri districts, especially in the latter. The appointment of special inspectors with local knowledge and status seems to be fully justified, and no doubt the Gorenment of India will in time make these appointments more general.

Instruction in Bacteriology for I.M.S. Officers.

In and after January, 1910, a course of training in clinical bacteriology and laboratory technique is to be made available for officers belonging to the Indian Medical Service at the Central Research Institute, Kasauli. Officers detailed for the course will be permitted to be absent from their stations for four weeks in addition to the actual time occupied by the journey to and from Kasauli, and one day for preparation for each journey. The classes of instruction will assemble in the months of January, March, May, July, September, and November each year. It is to be hoped that the Government of India will see its way to extend the same privileges to the other branches of the medical services in India.

Compulsory Quinine.

The Punjab Government has just issued a circular letter to all heads of departments and deputy-commissioners in the Punjab recommending anti-malarial measures and expressing the hope that during the next three months every endeavour will be made to carry them out. The plague staff has been asked to coöperate. The Punjab Government has also authorised the free distribution of quinine amongst all Government servants drawing less pay than Rs. 10 (13s. 4d.) per mensem, and has recommended the general and regular use of quinine amongst all other classes and ranks of officials. Those who do not take quinine regularly will not be entitled to the usual grant of leave given in case of sickness, if the illness is due to malarial fever, but will be subject to the ordinary leave rules.

Combined Leave Regulations for R.A.M.C.

The Government of India has decided that officers of the Royal Army Medical Corps holding executive staff appointments of limited tenure in India are eligible for combined leave under the provisions of A.R.I., Vol. II., para. 226, which allows of leave for a period of eight months or less on full pay for the first three months, and on ordinary pay for the concluding portion. The chief executive staff appointments open for R.A.M.C. officers in India are sanitary officers of divisions and divisional medical mobilisation. No record of executive staff service is made, however, for medical officers in the quarterly army list, although the same service is freely recorded for the most junior of the combatant branches.

Ocf. 19th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The late Mr. Philip Muskett.

THE death was announced in Sydney on August 25th of Mr. Philip E. Muskett, a well known practitioner in that city. Mr. Muskett was born in 1857 and qualified as L. R. C. P., L. R. C. S. Edin. in 1880. He was subsequently resident medical officer at the Melbourne Hospital and at the Sydney Hospital. He held various official posts in Sydney and was at one time honorary surgeon to the Sydney Hospital. The deceased gentleman was much liked in a large circle of friends, and was well known as the author of several quasi-popular works on dietetics and kindred medical topics.

Remarkable Poisoning Case.

A curious instance of poisoning due to carelessness occurred recently in Sydney. A visitor at the Hotel Arcadia drank a tumbler of water in his bedroom and expired very shortly afterwards. He remarked to his wife that the water tasted strangely. When the account of the occurrence appeared in the daily press a foreigner, who had occupied the same bedroom previously, communicated with the police and informed them that he had been experimenting with a solution for silvering glass and had left the tumbler in which he had seed some chemicals. The cause of death was cyanide poisoning. At the inquest the former occupant of the bedroom was committed for trial on a charge of manslaughter.

Rat Destruction.

Dr. B. B. Ham is determined that rat destruction will be as vigorous an objective of his rule in Victoria as it was in Queensland. He attributes the comparative freedom from plague of Victoria and South Australia to the species of rat and variety of rat-flea found in them. In Australia there are practically only two distinct species of rat—the common grey-brown or Norway rat, living in sewers, and the English rat that infests houses. Dr. Ham thought until recently that the house-rat did not exist in Melbourne but finds that he was mistaken, and urges that measures should be taken for its destruction. There is no legislation at present by which householders can be compelled to keep houses free from rats, and Dr. Ham may find it advisable to recommend the introduction of compulsory legislation in Victoria.

Hospitals and Police.

The Melbourne city coroner recently animadverted strongly on the action of the committee of the Women's Hospital in declining to give information to the police concerning patients in the hospital. The matter arose in connexion with an inquest on the body of an infant supposed to have been murdered. A detective in charge of the case had reason to suppose the mother had been treated at the hospital, but the committee declined to afford any information.

Subsequently the resident medical officer and the secretary were subprenaed and questioned by the coroner. In a leading article commenting on the coroner's remarks the Melbourne Argus upheld the action of the committee and considered the coroner's position mistaken.

Medical School Inspectors.

The Victorian Department of Education has appointed three medical inspectors, who will inaugurate a system of medical inspection of school children in the State. The salaries offered were £550, £500, and £450 per annum, and 35 applications were received. The final choice resulted in the appointment of Dr. Harvey Sutton, Dr. Mary Booth, and Dr. Jean Greig. Dr. Sutton has recently returned from Oxford, where he studied as a Rhodes scholar; and Dr. Mary Booth has had three years' experience as medical inspector in New South Wales.

Tuberculosis Conference.

A conference of local boards of health in South Australia has been held in Adelaide to develop means for better dealing with tuberculosis. The delegates were conducted over the Kalyra and Nunyara Sanatoriums and shown the consumptives' wing at the Adelaide Hospital Several proposals were left over for a further session, information being meanwhile supplied.

Nurses for the Bush.

At the annual meeting of the Women's National Council held recently in Brisbane the Countess of Dudley advocated an extension of the district nursing principle to outlying parts of the back country. The project has been warmly supported by Madame Melba who is at present in Australia. In order to form the nucleus of a fund to carry out a scheme of the kind, Madame Melba is arranging a special concert, the proceeds of which will be handed over to Lady Dudley. Oct. 14th.

Gbitnary.

RICHARD THEODORE STACK, M.D. DUB., F.R.C.S. IREL., L.D.S.R.C.S. ENG., D.M.D. HARV.

On Nov. 11th Dr. Richard Theodore Stack died at On Nov. 11th Dr. Richard Theodore stack died was his residence at Stillorgan, Ireland. Dr. Stack was born in 1849 and was educated at the Royal School, Raphoe, and the University of Dublin, where he graduated with honours, and in his senior Freshman year obtained a classical scholarship. In the medical school his career was one of great distinction. He obtained a medical scholarship, nearly every prize open to him, the first place in his degree list, and (an unprecedented honour)
a double travelling prize, which enabled him to visit the
Vienna Medical School, where he resided and studied for six months. On his return to Dublin Dr. Stack was appointed resident surgeon of the Richmond Hospital and alsoa demonstrator of anatomy in the University Medical School, and he seemed likely to climb to the top of his profession in Dublin. Unfortunately his hearing soon became defective, and recognising that the practice of either medicine or surgery could no longer be carried on by him with satisfaction either to himself or his patients, he determined with characteristic energy and pluck to go to America and join the Dental School in the Harvard University. Having obtained his degree, he returned to Dublin and commenced practice as a dentist with great success. Dentistry at that time-32 years ago-was at a very low ebb in the capital city; by Dr. Stack's tireless energy and enthusiasm new light and leading were infused into a neglected branch of the medical profession. It was partly due to his example that the whole position of dentistry was raised to the high position it now occupies, not only in Ireland, but in the sister countries. Dr. Stack was the founder of the first dental hospital and school in Ireland. He made himself responsible for the funds which built it, and organised one of the first and most successful of the bazaars which have done much from time to time to help the various hospital charities of Dublin. He was also dental surgeon to the Adelaide Hospital, Dublin. He had reached a high position in his adopted profession when he was suddenly struck down 11 years ago by a hemiplegia which deprived him of the use of his right arm, and greatly

interfered with his powers of speech. He, of course, had to retire from practice, but he never ceased to take an interest in the work and the Dental Hospital, in which his portrait, the gift of his colleagues on the staff, now hangs. He was a president of the British Dental Association and a member of the Royal Academy of Medicine of Ireland. Dr. Stack attracted towards himself many friends, and in the district of Mullaghmore his constant acts of charity and deep interest in the people won him their real devotion. For the past few months Dr. Stack's health was visibly failing. He knew the end was drawing rapidly near, and yet he faced death as he had all the difficulties of his life, with the fortitude of a true philosopher. His death was peaceful, and his body rests in his family burying-ground at Cappagh. He is survived by a widow who has received the deep sympathy of his friends, both in Tyrone and Dublin.

THE FEEDING OF LONDON SCHOOL CHILDREN. Assupplemental estimate of £25,000 was submitted to the Education Committee of the London County Council on Nov. 24th to meet the cost of providing meals for necessitous children. It was stated that many more children were being fed this winter than last, the numbers for the week ended Nov. 12th being 41,934 as compared with 22,430 in the corresponding period of last year. Some discussion arose on this report, one or two members expressing the fear that the meals were being given too freely. The Rev. Stewart Headlam, as a member of the Care Committee denied this, declaring that inquiries were unduly stringent. Miss Adler said the experience of the officials was that very few applications for assistance were made which were not warranted. Mr. Jay, an ex-chairman of the Care Committee, on the other hand, said that a large number of cases were put on the list by teachers which could not be regarded as urgent. He also called attention to the extent to which overlapping occurred owing to meals being given to children whose parents already received out-relief. The Care Committee was pressing the Local Government Board to advise on this point. Mr. Ernest Gray said it was the intention of the committee to proceed rigorously against all persons guilty of fraud in obtaining meals. The estimate was approved.

ROYAL DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and past and present students of the above institution was held in the Whitehall Rooms of the Hotel Métropole on Nov. 20th, when Mr. C. F. Rilot occupied the chair. After the usual loyal toasts had been received, the chairman proposed that of "The Past and Present Students of the Royal Dental Hospital and the Dental School." He gave an interesting retrospect of the history of the hospital and school, and referred feelingly to the old teachers who had passed away. He appealed to the past students to keep in touch with the institution, and in this connexion made some useful suggestions in regard to the value of the hospital Gazette. He thought it would increase the interest of this journal if past as well as present students would record in it now and again some features of novelty met with in their practice, and he should like to see the journal receive more support than it had hitherto received from those who had passed through the hospital and school. He could speak of the progress the school was making, and the teaching, organisation, and facilities were, he thought, second to none. The toast was responded to by a past student, Mr. E. A. Mansell, and a present student, Mr. G. Jackson, both of whom made excellent speeches, in which they expressed their appreciation of the excellent work done by the hospital and school. The recently appointed dean, Mr. W. H. Dolamore, replying for the staff, paid an eloquent tribute to previous deans, and said that much of the success of the school was due to their zeal and energy. The school was flourishing, there were 160 students on the books, and the spirit with which the work was entered into was admirable. Dr. R. J. Probyn-Williams proposed the toast of "The Visitors," to which Mr. H. R. F. Brooks, the President of the British Dental Association, replied. The last toast on the list, that of "The Chairman," was proposed by Mr. J. F. Colyer. The excellent singing of the "Westminster Singers" added considerably to the enjoyment of a very successful gathering.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, Nov. 23RD.

THE half-yearly session of the General Council of Medical Education and Registration opened to-day at the Council's offices, 299, Oxford-street, London, W. Sir DONALD MACALISTER, the President, was in the chair.

New Members.

Dr. JOHN DIXON MANN (introduced by Dr. R. CATON) took his seat at the Council as the representative of the Victoria University of Manchester.

It was officially intimated that Sir Christopher Nixon. Bart., had been appointed representative of the National University of Ireland for a period of three years from Nov. 11th, 1909.

The President's Address.

The PRESIDENT in delivering his address said: His Majesty the King in Council has been graciously pleased to approve and give effect to the representations which on May 25th you directed to be made, and which I duly communicated to the Privy Council. An Order has accordingly been issued which confers on the registered practitioners resident in England and Wales the power, at the next general election, of returning an additional member to this Council. Thus in about two years' time the directly elected representatives of the practitioners of England and Wales will number four, instead of three as at present. Our respectful acknowledgments are due to the Privy Council for their good offices in commending our request to His Majesty's favourable consideration. You will have learned with much pleasure that His Majesty has bestowed the dignity of a baronetcy on our treasurer, Sir Henry Morris, and on our late treasurer, Sir Dyce Duckworth. The Council will be at one with me in wishing that both our colleagues may long wear these merited honours in health and happiness. The tragic death of Mr. Sydney G. Lushington in the prime of his active powers has deprived the Council of an advise by whose legal skill and practical wisdom it has constantly profited during the past five years. When in 1904 the Council lost the services of Mr. Muir Mackenzie, owing to his official promotion, it felt deeply the withdrawal of an adviser on whose guidance it had confidently relied for some 25 years. On his recommendation we invited Mr. Lushington to act on occasion as assessor. We recognise to day that in thus advising us Mr. Muir Mackenzie rendered us a service which deserves our warmest gratitude. Session by session Mr. Lushington gained an ever surer place in our esteem, not only for his professional but for his personal qualities. He knew how to combine special knowledge with sound common sense, firmness with courtesy, and respect for precedent with open-mindedness in presence of new conditions. Many who knew intimately his character and attainments thought him destined for high office in his profession. To these friends, and to the members of this Council which he served so well, his untimely death brings more than regret for the interruption of a distinguished career; it brings also a sense of sorrow as for a personal loss. Acting on what I believed would be your desire, I arranged that the Council should be represented at Mr. Lushington's funeral; and I sent a message of sympathy and regret to his relatives, which has been gratefully acknowledged by them. As it was necessary to instruct counsel to advise us with reference to certain penal cases, and to act as assessor at inquiries to be held during the present session, I consulted Mr. Muir Mackenzie and our solicitor, Mr. Winterbotham, on the subject. By their advice Mr. A. H. Bodkin has been requested to give us his assistance during this week. Mr. Bodkin is familiar with the procedure of the Council, and he holds a public legal appointment under the Attorney-General similar to that previously held by Mr. Muir Mackenzie and Mr. Lushington. It should perhaps be explained for the benefit of new members that the Council has not hitherto. made any permanent appointment to the office of Judicial Assessor. Counsel is simply instructed from time to time in the customary way, as need arises. Before

the end of this meeting I shall take occasion to ascertain your wishes as to future arrangements in this respect. Another distinguished man, who for 10 years was honourably associated with the Council as the direct representative from Ireland, has passed away during the present month. Sir William Thomson, C.B., had won a prominent place among his brethren for his manifold services to the profession and to the State. Those who sat with him in this chamber will long cherish the memory of his impressive bearing and his helpful interest in the Council's work. On your behalf I have sent a letter of condolence to Lady Thomson and her We have to welcome, as a new member, Dr. John family. Dixon Mann, whom the Victoria University of Manchester sends to the Council in the place of Professor Young. He will find that his fame as a medical jurist has preceded him, and that the Council reckons with confidence on his ability to assist it in dealing with the questions, partly medical, partly juridical, which come before it. He will find also that the associations left by Professor Young are of so happy a character that it is already a recommendation to be his successor. We receive back Sir Christopher Nixon in a new guise, but with the old In May he sat as the member for the Royal cordiality. University of Ireland, of which he was Vice-Chancellor. The Royal University expired a few days ago, and with it his membership. But the National University of Ireland and the Queen's University of Belfast have now arisen in its stead. Sir Christopher returns with undiminished lustre as member for the National University, in which he is both professor of medicine and Vice-Chancellor. Under recent Acts of Parliament the Queen's University of Belfast and the University of Bristol have each acquired the right to appoint a Member of the Council, but the Registrar has not yet received intimation that the appointments have actually been made.

The movement for the application to the Provinces of the Dominion of Canada of Part II. of the Medical Act, 1886, continues to make progress. The Province of Prince Edward Island has now petitioned His Majesty in Council that the benefit of medical recognition, on reciprocal terms, may be extended to it. Negotiations on the question are proceed-ing, and as the Provincial law appears to afford due facilities for the local registration of all practitioners registered in the United Kingdom, a satisfactory agreement should be reached. A recent alteration in the Provincial law of Quebec appears to the Executive Committee to have the effect of limiting, in a manner which was not contemplated during the original negotiations, the recognition in Quebec of qualifications that are registrable in this country. As the question raised concerns in the first instance the Privy Council rather than the Medical Council, the attention of the Lord President has been called to it, and I have reason to believe that inquiries will be made through the proper official channels. We shall no doubt be informed of the result in due course.

The Committee, which were appointed to consider various proposals for legislation on the subject of anæsthetics, were informed officially that no progress was likely to be made with these proposals during the present session of Parliament. I therefore refrained from summoning the Committee to meet during the recess, but a meeting will be held during the present week, and a report on the subject will be prepared for your consideration. Meanwhile I was asked, as your President, to appear before a Departmental Committee appointed by the Home Secretary and give evidence regarding the action taken by this Council to promote the practical study of ansesthetics by candidates for medical qualifications. tions. I did so on Nov. 19th and laid before the Committee the relevant extracts from your minutes. The chairman of the Committee expressed the desire that any further resolutions which the Council may adopt during the present session might be communicated to him.

The objections taken last May by the Council, on legal grounds, to certain provisions in the proposed draft Charter of the British Medical Association, were communicated to the Lord President of the Privy Council for his information. There is reason to believe that our criticisms, and those offered by various other bodies, have been brought by his lordship to the notice of the Association. It is probable that an amended draft, in which account is taken of these criticisms, will in due course be substituted by the Association for the original proposal.

The report of the Education Committee on the distribution of the medical student's time, as between the several parts of the curriculum, will in accordance with your resolution be discussed. Its terms have been long before the Council, and have no doubt been carefully considered by members individually. It is to be hoped that the Council is now ready to discuss and to decide upon the important and yet simple proposals it contains for the improvement of medical education, more especially in regard to the branches of knowledge on which professional competence mainly depends. The Pharmacoposia Committee held a two-days' meeting last month for the consideration of the suggestions for the revision of the Pharmacopæia made by the several medical authorities with respect in particular to the omission or inclusion of specified drugs and preparations. With the assistance of the secretary, Dr. Tirard, the committee were able to arrive at provisional conclusions in a large number of instances. These will form the basis for further inquiry, and at a later stage will come up for definitive settlement. Meanwhile the Committee of Reference in Pharmacy continues its labours for the improvement, from a pharmaceutical point of view, of the several monographs in the present issue of the Pharmacopœia.

The November session is understood to be set apart especially for disciplinary inquiries. Owing perhaps to the more systematic notification by the civil authorities of offences and convictions in which professional men are concerned, we have on this occasion a considerable number of such cases to deal with. Some of these are of a novel character, and will call for your special attention. have been patiently studied by the Penal Cases Committee, with the help of our legal adviser, and in the light of the documentary evidence submitted. In every instance the committee has satisfied itself that there is a case which prima facic calls for an answer, and it has accordingly authorised the institution of an inquiry by the Council before which alone the case and the answer can be fully stated and supported by oral or other testimony. The question whether it is practicable in medical cases, as it is in dental cases, to delegate such inquiries, so far as the facts are concerned, to any body of members short of the full Council, has been occupying the attention of the Executive Committee. But in view of certain difficulties, as yet unsurmounted, the committee are not at present prepared to offer definite proposals for your consideration. In so important a matter it is necessary that the statutory responsibilities of the Council should first be fully ascertained and discharged. Even serious considerations of convenience and economy cannot be allowed to outweigh considerations of legal obligation, should these prove to be in conflict. Personally I express the hope that the Executive Committee may discover some way by which they may be reconciled.

The Indian Medical Service.

A return was received by the Council showing the results of the competition held in July, 1909, for commissions in the Indian Medical Service.

The Medical Curriculum.

Dr. J. Y. MACKAY moved the adoption of the recommendations contained in the report of the Education Committee on the distribution of the medical student's time as between the several parts of the curriculum. The recommendations of the report which was presented last session were as follows :-

report which was presented last session were as follows:—

For the purposes of this recommendation the subjects of the curriculum are arranged in two groups, the earlier group comprising the preliminary sciences and anatomy and physiology, the later group embracing all the remaining subjects, exclusive of pharmacy.

The regulations of the bodies should be so framed as to secure (1) for the study of the subjects of the later group the reservation of a period equivalent in value to 23 excelmic years (27 months) of undivided study, half time-value being allowed for periods of work in which studies in the earlier and later groups overlap; and (2) the reservation of a period of two accademic years (21 months), in which the studies of the later group shall have the undivided attention of the studient.

They had, he said, two definite proposals before them for the extension of the curriculum. One was the proposal that the curriculum should be extended to six years, and the other that the curriculum should be extended by means of a "block," or more than one "block," introduced at certain stated places, and the student prevented from passing a block until all his earlier subjects had been completed. Regarding the proposal that the curriculum should be lengthened to six years, he said this could only be carried out if there was a consensus of opinion on the part of experts in medical education that the extension was desirable. He thought that the general position was that the time was not ripe for the extension of the curriculum to six years. The committee had had brought to their notice no request from any of the great licensing and teaching bodies that the curriculum should be extended. He referred to the reports which the Council had received on the subject of the examinations conducted by the various bodies. In the Victoria University of Manchester 72 per cent. of the students completed in 5½ years. At Glasgow University, the examinations of which had been favourably reported upon, 56 per cent. of the students passed in 5½ years. It would be a very serious hardship if the Council were to delay men passing examinations when they were apparently well qualified to do so, and to impose upon them by any artificial rule a demand for a six years' curriculum. Many of the men passing so quickly were the best of their time. He would like to say for himself that, in his view, the best possible thing the licensing bodies could do was to say that their students after passing their examinations should spend six months of study in a properly staffed hospital. The average age, taking the whole country, at which students commenced their curriculum was 194 years. The average length of the course was 7 years, and the average age of qualification was 264 years. 34 per cent. of the men qualified in 5½ years, and the remaining 66 took six years or more. Council might well consider what would happen if they were to have a compulsory extension of the curriculum to six years. There were three possibilities to consider. If the standard of instruction and examination were raised entirely from a five years' level to a six years' level the change would affect all students. The men who passed in five years now would require six years, and the men who required six years now would need seven, and so on. There was a second possibility. The standard might not be raised. All that would happen then would be that some 34 per cent. of the men would be delayed in their curriculum. If they did somewhat increase the standard no doubt a part of the increase would go to the earlier subjects and not to the final subjects in which the Council was most interested. The Education Committee, therefore, did not propose at present that the curriculum should be lengthened. No doubt new subjects were constantly added to the medical course. The Council had recently decided that the teaching of anæsthetics should be carried on in a more thorough way than it had been in the past. The committee had also discussed the "block" system. There was no doubt that there had been undue encroachment on the final examination. The Education Committee regarded this state of matters as not being what it ought to be. The committee believed that the Council should lay down a fixed minimum period for final study. They had selected this minimum period as one of 27 months. They wanted to lay down the general proposition that half the course should be given to the final subjects. He did not think the Council could go the length of saying that overlapping should be abolished altogether, but he thought it could go the length of saying that overlapping must not go too far. The Education Committee had adopted as a principle that overlapping study should not be carried beyond the third year. It would, no doubt, be much simpler to say that the course should be divided into two parts, but it became necessary in view of actual circumstances to recognise an arrangement of overlapping. The proposal of the committee was not a drastic one, but it was very important. It would have three effects. It would ensure that the final examination would get its fair share of the curriculum. Further, the Council by taking this step would be claiming its position that it concerned itself with teaching as well as examination. Then if it passed these recommendations there would be a minimum for the final examination, and that minimum could be extended from time to time as the Council thought fit. There was a proposal laid before the Education Committee that there should be a "block" at two stages, and that preliminary sciences should be completed before physiology and anatomy were entered upon. The committee, however, thought it inadvisable to propose that a "block" should take place at that part of the course. They thought the block" should be established between physiology and anatomy on the one hand and the final examination on the other, and if that were done, enough would have been accomplished for the present.

Sir Christopher Nixon seconded.

Sir Hugh Beevor asked what percentage of the students who were examined would be affected by these regulations.

Dr. MACKAY said it would not be a very large percentageprobably 4 or 5 per cent.

Dr. NORMAN MOORE said they were all agreed that the whole object of medical education was to obtain a knowledge of medicine, surgery, and midwifery. How could that object best be obtained? The final branches of instruction could not be fully beneficial to the student unless he spent a sufficiently long time upon them. The reason for recommending a long period for the final studies was that their acquisition must be by a very slow and gradual method. If the Council accepted the report, it did no more than say that a long period ought to be given to final studies, and that period ought not to be invaded by any other subject whatever. He hoped that the Council would strongly support the view that the final studies would be allowed a definite uninvaded period in the regulations by the qualifying bodies.

Sir CHARLES BAIL pointed out that there were some circumstances regarding the Dublin students which did not apply in the same way to the English and Scotch students. There had been a custom for many years in Dublin for a very large number of students, including the very best students to take a period of residence at a hospital as a pupil for four or six months. That was far better experience for them than could be obtained by attendance three or four hours a day. In the Dublin University they had for a year or two adopted the "block" system, and so far as their experience went it was very satisfactory. The "block" put on at Dublin was that a man must pass the examination which in normal circumstances should be passed at the end of the second year before he commenced his course at the beginning of the fourth. Hospital practice was commenced in the second year, and the body which he represented would hesitate to support any arrangement which would interfere with students becoming resident pupils.

Sir THOMAS MYLES expressed concurrence with the recommendations of the committee, but urged that they should be

framed with a certain amount of elasticity.

Dr. R. SAUNDBY said that his opposition to these proposals went further than had been expressed by any previous speaker. He did not like hard-and-fast ruleswater-tight compartments from which there was no escape. He very much regretted that after all these years which the Education Committee had spent considering this matter, they only brought up such an insignificant and unimportant recommendation. Those them who were final teachers could not be satisfied There were a good with medical education as it was now. many men who were allowed to go into the profession whose preliminary education was defective. Men who came for instruction in medicine and surgery often showed that the had no adequate knowledge of chemistry, anatomy, or physiology. They seemed to think that those subjects. having been passed, should not be longer kept up. That showed the defect of the present method of medical education, and the more they adopted water-tight compartment, the more encouragement would they give to it. They wanted to get men to the final examination with a knowledge of physiology and anatomy. He further protested against the growing practice of allowing students to take their examinations piecemeal.

Sir THOMAS FRASER said that the body which he represented expressed its warm concurrence with these recommendations They agreed that there should be a certain amount of latitude. In Edinburgh University students came from the colonies and from India, and a large number of these men from India had already attended three or four years in reputable institutions. They came to Edinburgh to get their degrees and had to pass all the examinations there. It would be very undesirable to ask them to comply with the requirements of the "block" system. Cases of that description cought to be attended by system. description ought to be attended to. At the same time thee whom he represented thoroughly concurred in the recom He thought that the Council mendation as to the "block." would make a great mistake if it placed too much emphasis on hospital and clinical work. It was most valuable to train the intellect of the men so that they would afterwards be able to obtain a very complete knowledge for the practice of midwifery, medicine, and surgery. He thought the stodent

would be all the better in his after career if not too much emphasis was laid on hospital work.

Sir HENRY MORRIS pointed out that only 13.8 per cent. of medical students passed through their curriculum in five The majority of them took 6 years and 11 months.

Sir CHRISTOPHER NIXON thought that at the present stage the recommendations of the committee were the most practical that could be passed by the Council, although personally he would have been in favour of something more. He dissented from what had been said by Sir Thomas Fraser.

Dr. NORMAN WALKER moved the adjournment of the debate, and this was agreed to.

The Council then adjourned.

WEDNESDAY, NOV. 24TH.

The Council resumed and most of the sitting was occupied in the consideration of penal cases.

Medical Rews.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. The annual meeting of the Fellows and Members was held on Nov. 18th at the College, Mr. Butlin presiding. A report of the proceedings will be published in THE LANCET. At the First Professional Examination for the Licence in Dental Surgery the following gentlemen were approved in the subects indicated below

Surgery the following gentlemen were approved in the subjects indicated below:—

Mechanical Dentistry and Dental Metallurgy.—Ernest Walter Bacon, Guy's Hospital; Harold Barrett, Royal Dental Hospital; Victor Emanuel Dawson Bergh, Guy's Hospital: William Reginald Brandon, Manchester University; Eric James Moore Charter and John Stanley Cocks, Guy's Hospital; Arthur Caspar Stevenson Cottam, Royal Dental Hospital; Arthur Caspar Stevenson Cottam, Royal Dental Hospital; Graham Cotterell, Birmingham University; James Kenneth Crawford, Royal Dental Hospital; Reginald Gilbert Farrington, Guy's Hospital; William Ewart Halliana, Royal Dental Hospital; George Gerald Jack, Royal Dental Hospital; Ernest Victor Jones and Theodore Hesketh Jones, Royal Dental Hospital; Lonel Seott Langley, Guy's Hospital; Harold Woodhead Mawson, Leeds University; Bertie Mendleson and Roy Harry Barkly Pallett, National Dental Hospital; John Griffith Richards, Russell Rodgers, and Hubert Dennis Shore, Guy's Hospital; Francis Henry Smith, Hugh Dynevor Stephens, and Oscar Henry Titmas, Royal Dental Hospital; John Griffith Richards, Russell Rodgers, and Hubert Dennis Shore, Guy's Hospital; Francis Henry Smith, Hugh Dynevor Stephens, and Oscar Henry Titmas, Royal Dental Hospital; Thomas Reginald Trounce, Guy's Hospital; Ernest Victor Breen Turner, Liverpool University; Douglas Wain, Geoffry Heegaard Warner, and Clifford Toulson Watson, Guy's Hospital; Alan Ayscough Wilkinson, Birmingham University; William Jefferson Wilkinson, Pennsylvania University; John Fitzgerald Williamson, Royal Dental Hospital; John Grussell Hospital; John Wilfrid Hall, Birmingham University; Robert John Harley-Mason and Lawrence Richards Haydon, Royal Dental Hospital; Harold Hospital; Harold Hospital; Harold Hospital; Harold Hospital; Hospital; Henry James Burch, Guy's Hospital;

UNIVERSITY OF LONDON.—At examinations ald in October the following candidates were successful: THIRD M.B., B.S. EXAMINATION.

Hind M.B., B.S. Examination.

Honours.—†Emile Marc A. Duvivier, Guy's Hospital; †Geoffrey Jefferson, Victoria University of Manchester; †Guy Harcourt Peall, Guy's Hospital; *†Harry Platt (University Medal), Victoria University of Manchester; *William Rees Thomas, Charing Cross Hospital; †Ernest Frederick Gordon Tucker, London Hospital; and *Joseph William James Willcox, University of Bristol.

Pass.— Malcolm Edward Ball and Richard Pitt Ballard, Guy's Hospital; Ella Mabel Barker, London (Royal Free Hospital) School of

Medicine for Women; Alfred Bernstein, Victoria University of Manchester; Benjamin Biggar, St. Bartholomew's Hospital; Anne Borrow, London (Royal Free Hospital) School of Medicine for Women; Hugh Leonard Burton, King's College Hospital; Herbert D. Clementi-Smith, St. Bartholomew's Hospital; Arthur Davies, Westminster Hospital; Maurice Rowland Dobson and Raymond Charles Viner Bdsall, Guy's Hospital; Arthur Oxley English, Middlesex Hospital; Eric Leigh Fyffe, St. Thomas's Hospital; Arthur Atkins Greenwood, Guy's Hospital; David John Harries, University College Hospital; Charles Reginald Hoskyn, St. Bartholomew's Hospital; William Stanley Hughes, St. Mary's Hospital; Maurice L. Corrie Irvine and Walter Burford Johnson, St. Thomas's Hospital; John Edward Lionel Johnston, St. Mary's Hospital; Robert Henry Hatten Jolly, Charing Cross Hospital; Bertram Arthur Lloyd, University of Birmingham; George Gibson Lyttle, Queen's University. Belfast; Elias Leopold W. Mandel, Guy's Hospital; Edgar William Matthews, King's College Hospital; Edwin Bertram Morley, London Hospital; John Sherwood New, St. Bartholomew's and University College Hospitals; Arthur Henry Penistan, London Hospital; William Joseph Petty, St. Thomas's Hospital; Cecil John Rogerson, University College Hospital; Francis Charles Searle, St. Bartholomew's Hospital; Charles Woolley Shepherd, Charing Cross Hospital and University College, Cardiff; Gravenor Robert Strong, Westminster Hospital; John Balley Tackaberry, Middlesex Hospital; Margaret Grace Thackrah, B.A., London (Royal Free Hospital) School of Medicine for Women; James Richard Henry Turton, St. Bartholomew's Hospital; Richard Tudor Williams, St. Bartholomew's Hospital; Ernest William Mitney, St. Thomas's Hospital; College Hospital; Richard Tudor Williams, St. Bartholomew's Hospital; Ernest William Mitney, St. Thomas's Hospital; College Hospital; Richard Tudor Williams, St. Bartholomew's Hospital; Ernest William Mitney, St. Thomas's Hospital; College Hospital.

Distinguished in Medicine

* Distinguished in Medicine. † Distinguished in Surgery.

The following candidates have passed in one of the two groups of subjects :-

Group I.—Jackson Arthur Atkinson. St. Mary's Hospital; Alfred David Eldred Bayliss, University College Hospital; Henry William Catto, Guy's Hospital; Ethel Mary Connan and Nina Gertrude Cotton, London (Royal Free Hospital) School of Medicine for Women; James Philip Elias, Victoria University of Manchester; Edgar Lionel Elliott, Guy's Hospital; William Moses Feldman, London Hospital; Dossibal Rustomji C. Patell, London (Royal Free Hospital) School of Medicine for Women; Wilfrid Langrish Pink, St. Thomas's Hospital; Arthur Haig Pollard, London Hospital; Geoffrey Price, St. Thomas's Hospital; Simon Isaac Rabbinowitz, London Hospital; Ernest Edward Andrew T. Rigg, University College Hospital; Harfy Dudley Rollinson, University of Birmingham; and Robert Heywood Wilshaw, Victoria University of Manchester.

Manchester.

Group II.—Mary Howard Atherton, London (Royal Free Hospital) School of Medicine for Women; George Henry Chisnall, London Hospital; Philip Crawford Conran, Middlesex Hospital; Robert Lawson Crabb, University College Hospital; Josiah Rowland B. Dobson, University College, Cardiff, and St. Bartholomews; Hospital; Douglas Green, University of Sheffield; Arthur Rocyn Jones, David Kennedy, and John Stephen Herbert Lewis, University College Hospital; Joseph Pearson Little, London Hospital; Etael Mary Morgan, London (Royal Free Hospital) School of Medicine for Women; Hubert O'Meara, University College Hospital; Arthur Borland Porteous, St. Mary's Hospital; George Francis Rawdon Smith, University of Liverpool: Tom Stansfield, Guy's Hospital; Norman Tattersall, Victoria University of Manchester; Gottfried Oram Telchmann, Middlesex Hospital; and Walter Weir, St. Thomas's Hospital and Epson College.

N.B.—This list, published for the convenience of candidates, is issued ubject to its approval by the Senate.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated:

Surgery.—B. T. Lang (Sections I. and II.), Cambridge and St. Bartholomew's Hospital.

Vignolo-Lutati of Bologna has been recognised as privat-docent of Dermatology.—Vienna: Dr. Uhthoff of Breslau has declined the chair of Ophthalmology vacated by the death of Dr. Schnabel; Dr. Wilhelm Mitlachen, privat-docent of Pharmacognosis, has been promoted to an Extraordinary Professorship; Dr. Karl Reiter has been recognised as privat-docent of Medicine; and Dr. Hans Lauber as privat-docent of Ophthalmology. - Würzburg: Dr. Adolf Treutlein, who was until about a year ago privatdocent of Military, Naval, and Tropical Hygiene, accepted an appointment as Director-General of the Health Department of the Government of Bolivia, but having found his post untenable on account of political and financial troubles has now returned to his former position on the University staff.

THE NATIONAL DENTAL HOSPITAL.—On Friday evening, Nov. 19th, Sir Thomas Barlow, Bart., K.C.V.O., presided at the annual dinner of the past and present students of the National Dental Hospital, which was held at the Trocadero Restaurant, Piccadilly, W. The toast of "The having been drunk with musical honours, Sir Thomas Barlow proposed "The National Dental Hospital and College," with which he coupled the name of Mr. Sidney with which he coupled the name of Mr. Sidney Spokes, the dean. He commenced his speech, which was listened to with marked attention, by referring to the inadequate support which dental hospitals received from the public. Dealing with the inspection of school children he said that no other educational legislation was so important as the enactment in regard to this matter. The medical inspection of school children had in it an enormous potentiality which the medical profession would do well to accentuate and drive home. If this were done the next generation would see their people much more physically efficient than the present one. The arrangements made for the care of the teeth of the children were of the utmost importance, and he appealed to both past and present students of the Dental Hospital to help the educational authorities in every possible way. At the same time the labourer was worthy of his hire, and that should not be forgotten by workmen's clubs and municipal authorities. It was extremely difficult to get those who were uneducated in the subject of the care of the teeth to realise its extreme importance, but if once the matter became well under way then even if the remuneration were but meagre and inadequate at first time would justify the result, and in the end the dentist

would be on a better footing. Speaking of dental work generally, he pleaded for a more intimate connexion between the dentist and the medical man. The medical student and the dental student began their work side by side, he said; medicine and surgery were in need of dentistry, and dentistry could not get on without surgery. The collateral working of the three branches was for the benefit of the patient. He also desired to see a wider field in medical research which should not be restricted to the few but should even find a place in the teaching of students. That would be for the good of humanity. Mr. Spokes, in replying, said that certain structural arrangements in the hospital were contemplated in order that the building might be more efficient, and he appealed to all present to assist in raising the necesary funds. Even if they were unable to do so personally they might do so indirectly by pointing out when suitable opportunities occurred the importance of the work done by the hospital. The dental surgeon was quite willing to do his share of the public work involved in the inspection of school children, but when as the result of an enlightened public opinion the demand was made for an adequate supply of dentists it would be found that there were not enough dentists to do the work. Until the public made the demand they could not expect to get the supply. The medals and certificates won by the students during the session 1908-09 were then handed to the successful competitors by Sir Thomas Barlow. Mr. C. Stacey won the Ash prize, Mr. C. L. Donne and Mr. C. Stacey the Cottrell prizes, and Mr. Donne the Rymer medal. toast of the "Past and Present Students" was proposed by Dr. Dudley Buxton, who pointed out that it was a dentist who first discovered nitrous oxide, and a dentist also who that he was not fit to use it. Mr. Sidney Rose and Mr. Cecil L. Donne replied. Dr. H. P. Noble proposed "The Visitors." which was responded to by Mr. F. S. Eve. Dr. James Maughan proposed "The Chairman." A well-rendered musical programme added to the pleasure of an enjoyable evening.

LIVERPOOL HOSPITAL SUNDAY thirty-ninth annual meeting of the Hospital Sunday Fund was held at the Town Hall on Nov. 10th, the Lord Mayor presiding. The receipts from the collections made on Hospital Sunday of 1909 were £6235 18s. 5d., against £6423 15s. 4d. in 1908, being a decrease of £187 16s. 11d. The total amount available for distribution was £6333 12s. 5d... and of this sum £6297 17s. 3d. had been paid over to the joint Hospital Sunday and Saturday Fund, while a balance of £35 15s. 2d. had been carried forward. alluded to the fact that each year the hospitals throughout the city were spending large sums of money to increase their accommodation in the most scientific manner. The recent rebuilding of the Children's Infirmary, the new dentahospital, the new out-patients' departments in connerion with the Royal Infirmary and Royal Southern Hospital, at additional operating theatre at the David Lewis Northern Hospital, the proposed rebuilding of St. Paul's Eye Hospital, and the New Maternity Hospital, all bore witness to the keenness and enthusiasm of the citizens in providing the best that could be obtained to relieve the suffering poor. The committee desired to thank Mr. George Nicholson for his generous offer to bear the entire cost of the expenses of the Hospital Sunday Fund for this year, thus enabling the committee to distribute every penny contributed to the fund. Sir William H. Tate, Bart., kindly offered to guarantee the amount of the expenses during the coming year, not exceed-The honorary treasurer deplored the fact ing, say, £250. that the total amount distributed by the joint Hospital Saturday and Sunday Fund was £1500 less than last year.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Housing and Town Planning Bill.

THERE is now every prospect of the Housi g and Town Planning Bill reaching the Statute-book this year. Conciliatory influences have prevailed, and the House of Lords has accepted in almost every respect the plan of concessions suggested by the President of the Local Government Board in the House of Commons. The result is that some of the provisions of the Bill now represent a compromise. The Housing and Town Planning Bill has been before Parliament for two sessions. Last year it was subjected to a minute examination at the hands of a Standing Committee of the House of Commons, but no time remained to pass it through all its stages and to send it to the Lords. The intention of the Government to press it forward early this year was frustrated by the pressure of other business. However, they felt themselves pledged not to allow another session to pass without a serious attempt to place it on the Statute-book. After the Commons had passed it under a closure resolution it reached the Lords at a comparatively late date in the session. In the Upper Chamber it was so greatly amended in committee that at one time it was feared that the Government would abandon it. However, as the result of mutual concessions its passage is now assured.

Many medical men will be gratified that the Lords have not insisted on their amendments in the clause relating to the medical officers of county councils. On Friday, the 19th, the House agreed to the reinsertion of the section providing that the medical officer of health of a county should only be removed with the consent of the Local Government Board. The Commons inserted a provision in the clause that the duties of a medical officer of health of a county should be such duties as might be prescribed by general order of the Local Government Board and such other duties as might be assigned to him by the county council. This has also been accepted by the Lords, but a new subsection has been added that the general order prescribing these duties should be laid before Parliament.

HOUSE OF COMMONS.

TUESDAY, NOV. 23RD.

The Indian Medical Service.

The Indian Medical Service.

Mr. Hazleton asked the Under Secretary of State for India what was the percentage of Indians amongst the officers of the Indian Medical Service; what was the total cost for the upknep of this service; what was the charge on the Indian Treasury for recruiting the higher grades of the medical service of India in this country, and sending the successful candidates to India; what was the number of officers who were on leave every year and the cost of the extra number taken into the service during their absence owing to Indian assistant surgeons not being allowed to take their places; and when he proposed to open the higher grades to qualified and capable Indians.—The MASTER OF ELIBANK replied: The percentage of Indians (i.e., pure Asiatics) among the officers of the Indian Medical Service is rather more than five. The total cost of the officers of this service on the active iist, including both those in military and in civil employ, is approximately £570,500 a year. The charge for recruiting these officers,

both European and Asiatic (both being recruited in England) is about £12,280 a year, which includes the pay of the officers while under training in England. The average number on leave may be taken as 123. The vacancies so arising are filled from the establishment and not by extra appointments. The higher grades are already open to qualified and capable Indians.

Vaccination in the Army.

Mr. John Ward asked the Secretary of State for War whether the exemption of the Territorial Forces from compulsory vaccination had had any effects detrimental to the health of the men; and, if not, whether he would issue orders to respect the conscience in this matter of recruits to both branches of His Majesty's Forces.—Mr. HALDANE replied: No statistics are available at the War Office to enable me to reply to the first part of the question. As regards the second part of the question, there is no intention of waiving the regulations regarding vaccination in the regular forces.

WEDNESDAY, Nov. 24TH.

The Royal Army Medical Corps in Ireland.

The Koyal Army Medical Corps in Ireland.

Mr. Ashley asked the Secretary of State for War whether steps were being taken to ensure that officers of the Royal Army Medical Corps serving in Ireland should this year receive the full leave to which they were entitled by the Regulations.—Mr. Haldhar answered, in accordance with a previous written reply (The Lancer, Nov. 13th, p. 1477): Under normal conditions it will now be possible to give every Royal Army Medical Corps officer serving in Ireland throughout the year full leave, provided that he is willing to take it when the exigencies of the service permit. service permit.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANGET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

Rotes, Short Comments, and Answers to Correspondents.

A COMPARATIVE RESEARCH UPON VARIOUS LOCAL ANÆSTHETICS: THE PERILS OF COCAINE.

To the Bulletin des Sciences Pharmacologiques M. J. Chevalier has recently communicated the results of a series of tests which he has made to determine the comparative value of several of the leading local anæsthetics. The substances examined included cocaine, tropacocaine, stovaine, alypine, anæsthesine, and novocaine. As regards their general action these substances behave, he said, similarly and manifest identical phenomena. They act chiefly on the central nervous system and particularly on the bulb, producing, in toxic doses, general analgesis, tonico-clonic convulsions, and finally death by asphyxia. They differ from each other only in toxicity and in the intensity of their local action upon the blood and tissues. The following table gives the toxic dose in grammes of each of these substances when injected into various animals:—

Animal.	Mode of Injection.	Cocaine.	Stovaine.	Anas- thesine.	Novo- caine.	Alypine.	Beta- eucalne.
Guinea- pig.	Interperi- toneal.	0.08	0.18	0.85-0.90	0.50	0.16	0.24-0.26
Cat.	,,	0.03	0.11	••	0.45	0.057	••
Dog.	.,	0.05	0.12	0.75	0.48	0.06	••
"	Intra- venous.	0.003	0.10-0.13	0.40	0.50	0.002	0.05-0.06
,,	Subcu- taneous.	0.04	0.12	••	0.45	0.07	0.30-0.35

From these figures it is evident that cocaine is by far the most toxic of the commonly used local anæsthetics. M. Chevalier makes the interesting statement that these substances do not exert a general action, except cocaine, which induces euphoria with nervous and muscular stimulation. Turning to the action of these substances on the heart, he points out that cocaine differs from the rest in causing a rise in blood pressure, owing to its general and local vaso-constrictive power. Of the other local anaesthetics, stovaine most nearly approaches cocaine in this respect, but it has no action on the vasomotors. Beta-eucaine is a very energetic cardiac depressor, and for this reason its toxicity is greatly increased when it is rapidly introduced into the circulation. As regards the mechanism of the local anæsthetic action of these substances, M. Chevaller suggests that it may be due to an incomplete and transient coagulation of the albuminoids, causing a modification of the osmotic tension of the cellular fluid. In this way the normal functions of the living protoplasm are suspended, the sensitiveness of the nerves is deadened, the nerves endowed with motor and trophic functions are temporarily affected, and the respiration of the tissues is modified. On this account novocaine has been used to hinder the nutrition of cancerous These phenomena are accentuated when the local anasthetic is combined with the active principle of the suprarenal glands, the intense vaso-constrictive action of this substance greatly lowering the cellular vitality which has already been modified by the local anæsthetic. A further reason for the increased anæsthetic action of the combination lies in the fact that the action of the anasthetic is localised around the seat of injection, the diffusion of the liquid being prevented by the temporary suspension of the circulation. Cocaine and tropacocaine do not exert any marked action on the red blood corpuscies, but the other substances tend either to destroy them or to modify their power of resistance. From a therapeutic point of view M. Chevalier considers that many of the local anaesthetics are capable of yielding satisfactory results when properly used, but that it is a matter for discussion as to which of them is the best. Assuming that the value of a local anasthetic depends upon its anasthetic power, toxicity, and freedom from local irritation, he places stovaine and novocaine along with cocaine. He thinks the latter will continue to be used, in spite of its toxicity and the accidents caused by its intense vaso-constrictive action. Alypine causes irritation, beta-eucaine is too toxic, while anæsthesine is not sufficiently soluble. From a consideration of therapeutic results he finds it difficult to choose between stovaine and novocaine. Many surgeons prefer stovaine for important operations and for producing medullary anosthesia, while dentists give the preference to novocaine, which they are able to combine more easily with suprarenalin.

"WOMAN AT HOME."

AMONGST the "Christmas" papers and magazines which we have received is a double number of Woman at Home, a brightly edited paper dealing with many feminine interests. We have been particularly interested in an article by Marion Francis Neil on "The Art of Making Poultices," which should be of real value, as the art is quite unknown to many people who are called upon to practise it. The directions for linseed and mustard poultices are excellent, though we cannot entirely endorse the suggestion that people subject to "bronchial attacks" will gain much good by carrying dry mustard poultices with them on their travels. We would rather the author had omitted the bread poultice, which is always messy and generally ineffective; it might well have been replaced by a description of the useful turpentine stupe. The other articles in the magazine hardly come within our purview, unless we utter an anatomical growl at the conventional "fashion-plate ladies" on the back pages, but this would hardly be fair, as they are redeemed by some excellent photographic representations of living models in a special fashion supplement.

"DR. GUILLOTIN."

To the Editor of THE LANCET.

Sir.—The citation from Lenotre's book by Dr. Oscar Jennings does not, I think, quite invalidate the claim I have attempted to establish. Dr. Guillotin's remarks in the Constituent Assembly on Dec. 1st, 1789, do not appear to have been regarded seriously; the Moniteur, in describing the scene, said they were received with much merriment. It seems tolerably clear that the instrument which subsequently obtained such notoriety was designed by Dr. Antoine Louis, was constructed under his supervision, and for some time bore no other designation than La Louisette. When Dr. Louis presented to the assembly a report announcing the completion of the task imposed on him to produce a decapitator which would work automatically and instantaneously he made no reference whatever to Dr. Guillotin. Dr. Louis may have taken as a rough model a beheading machine employed in France some centuries before the Revolution or he may have been indebted to illustrations of similar machines anciently used in other countries—e.g., the Mannaia in Italy, the Hobel in Germany, the Halifax in England, and the Maiden in Scotland.

I am, Sir, yours faithfully,
Worthing, Nov. 15th, 1909. WATKIN W. JONES.

A SIMPLE LEDGER FOR MEDICAL PRACTITIONERS.

Mr. H. K. Lewis, 136, Gower-street, London, W.C., sends us a copy of a medical ledger which has been designed to meet the requirements of the busy practitioner who wants a simple and compact system of bookkeeping. It is a combination of day book and ledger, the first part being set out for daily entries, and the second part, which is indexed alphabetically on the margin, for monthly and yearly totals. At each opening in the first part are columns for entry of pape in case book, name, address, records of 31 visits, total fees for month, amount received and date of payment, amount carried to yearly summary, and memoranda. The ledger has been arranged so that the labour involved in bookkeeping is reduced to a minimum, and it would be hardly possible to devise a simpler and yet more complete scheme. It can be commenced at any date, and is intended to last a year, but in many cases would be serviceable for a longer period. The page is quarto size and the binding is stout. The publisher informs us that a copy will be forwarded for inspection if desired. The price is fance.

PRINTING "IN REVERSE."

To the Editor of THE LANCET.

SIR.—Some persons whose sight is impaired can read white letters on a black ground more easily than black on white. I know one gentleman who writes habitually on black paper with white ink. Printing "in reverse" is somewhat troublesome, but if many customers were forthcoming publishers would doubtless meet the want. I shall be glad to hear from anyone interested in the subject. A trial can be made with one of the numerous advertisements now printed in reverse, or I would gladly send a specimen.—I am, Sir, yours faithfully,

AMATEUR PRINTER, M.D.

29, Woolwich Common, Nov. 23rd, 1909.

A NEW SERIES OF NOTE-BOOKS.

THERE is no doubt that the best system for taking and filing lecture notes is one in which separate leaves of the note-book can be detached and arranged easily for subsequent reference. Messrs. John Walker and Co., of Farringdon House. Warwick-lane, London, E.C., have issued a series of "Expert Manuscript Books" which present the great advantage that a student need take only one note-book to a round of lectures, subsequently transferring each batch of notes to a separate binding cover in which they can be readily numbered and fixed. The eries is made in several sizes from octavo up to full quarto, and the binding cases are covered in stiff coloured canvas, having inside them an ingenious hinged metal clip which receives the actual MSS, book, which can be had either plain or ruled in various styles. The book is kept secure by two stout pins that transfix corresponding holes bored through its thickness near the back margin. Each leaf is perforated so that it may be torn out after use, and in front of the perforation are two other large holes which enable it, after its removal from the book, to be fastened into a special binding case in a similar manner. Thus by degrees, if such a transfer binding case be devoted to each lecture subject, a series of manuscript books will be built up, all of which may be fed from one single working note-book. The series deserves popularity amongst medical students who have to attend so wide a ran e of classes.

A "NATURAL" FEEDING-BOTTLE.

Mr. W. E. Lowe, of 8, Stafford-street, Old Bond-street, W., has sent us an ingenious feeding bottle for infants known as the "Amater" which has been made to the design of Mr. W. J. Henson, L.M.S.S.A. whose aim has been to imitate the mechanism of the actual breast and so to prevent the infant from sucking in air. The bottle is spherical except for the bottom, which is flattened to enable it to stand upright. At the opposite pole is a wide neck over which fits the rubber teat, which has a broad shield at its base Near the neck is a small air-hole in the glass which can be regulated exactly by the finger so as to control the flow of milk, which when the bottle is held in proper position bulges out the whole teat and causes it to resemble a breast in both contour and softness. The teat can be turned inside out and thoroughly cleansed without the use of a brush, and the inside of the bottle being free from all angles is readily sterilised in a small saucepan. Mr. Henson states that he has had such bottles in use for a considerable time, and the success of the trial which was made with the specimen sent us thoroughly warrants our bringing it to the notice of our readers.

R. H.—The combination of the tinctures of strophanthus and digitalis is quite unobjectionable and sometimes proves extremely useful. Our respondent might with confidence add Tr. digitalis, m v., to the mixture which he is employing.

G.P. has failed to substantiate his communication with his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Beek.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—George C. Cathcart, L. Hemington Pegler): at 5 P.M.

Cases and Specimens:
Dr. Dundas Grant: (1) Epithelioma of the Palate and Left
Pillar of the Fauces; (2) Secondary Specific Pharyngitis in

Pillar of the Fauces; (2) Secondary Special First yields of the Fauces; (2) Secondary Special First young Female.

Dr. W. H. Kelson: Suppuration in Frontal Sinus and Necrosis.

Mr. H. Betham Robinson: (1) Left Abductor Paralysis in a Young Man-presumably Toxle from Lead; (2) Chronic Laryngitis with Curlous Appearance of Right Vocal Cord.

Dr. Scanes-Spicer: Model by which the Variation in Effect of Costal (back) and Abdominal (belly) Breathing on the Stresses, Strains, and Frictions in the Throat and Larynx, more especially of Cricoid Cartilage on the Spinal Column, and also the Transverse Axis of Respiratory Rotation of the Cricoid on the Thyroid Cartilage, can be illustrated.

And other Cases.

SECTION OF ANASTHETICS (Hon. Secretaries—Liewelyn Powell, R. W. Collum): at 8.30 p.m.

aper:
Mr. Bellamy Gardner and Dr. Salusbury Trevor: Lymphatism,
with specimens and lantern illustrations.

OTOLOGICAL SECTION (Hon. Secretaries-Hunter F. Tod, H. J. Marriage): at 10 A.M.

Cases:

Dr. Edward Law: Deafness and Discomfort in the Right Ear as Early Symptoms in a Case of Epithelioma originating near the Right Eustachian Tube.

Mr. Herbert Tilley: A Case of Audible Tinnitus.

Mr. W. Milligan: Demonstration of Haye's Pharyngoscope.

Mr. Richard Lake: A Short Paper on the Post-operative Tests in Right Cases of Labyrinthine Disease.

Dr. Albert Gray: A Contribution to the Study of the Pathology of Deafmutism (with lantern slide demonstration).

Mr. Sydney Scatt: Microscopical Sections through the Mastoid Antrum in a Fatal Case of Scarlet Fever demonstrating Streptococcus Conglomeratus in Situ. Brief Notes of the Case with Description of Histological Technique.

And other cases.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed suchricely "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FIGATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager.

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able .o effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

Until the end of the present year copies sent by post will be charged at the rate of $7\frac{1}{2}d$. inland and 8d. abroad.

Commencing with the issue of Jan. 1st, 1910, the rates of subscriptions, post free from THE LANCET Offices, will be :-

FOR THE UNITED KINGDOM.
One Year £1 1 0
Six Months 0 12 6
Six Months 0 16 6
Six Months 0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Situations wanted: First 30 words, 2s. 6d.; per additional 8 words, 6d.
Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.

An original and novel feature of "THE LANCET General Advertiser," is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded
Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager,
Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom, Advertisements are also received by them and all other Advertising Agents.

An Address

LOOKING BACK;

A GLANCE FROM EMPIRICISM TO EXPERIMENT. FROM SUPERSTITION TO RESEARCH.

Delivered before the Middlesen Hospital Medical Society on Nov. 11th, 1909,

BY SIR HENRY MORRIS, BART., M.A., F.R.C.S. Eng.,

EMERITUS LECTURER ON SURGERY AT THE MIDDLESEX HOSPITAL.

GENTLEMEN, -When, through the honorary secretary, your society paid me the compliment a fortnight ago to ask me to give the opening address of the session, my mind reverted to the past, to the long ago, and at once assumed

the attitude of looking back.

I remembered that in my earliest days at the hospital, in the first years of the "seventies" in fact, I held the office which our chairman holds now, of President of the Middlesex Hospital Medical Society. I recalled with what satisfaction I learnt that this society, founded as it was in 1774, is one of the oldest of the medical societies in London, and I began to reflect upon the vast changes in medical opinion, in professional knowledge, and in curative science which have occurred not only since the birth of this society, but in the much shorter period since the time when I was President. And if I may state in five words the chief cause of those changes, I will make use of the expression of (I think it was) John Donne, a poet and divine in the reign of James I., and say that they are due to "the sacred hunger of science." And if I were asked, "What kind of science?" I would answer, "Physical science which searches after truth by the method of experiment," that science which seeks for knowledge without first asking what direct or tangible benefit is likely to be derived from it. In the fields of research there is nothing to distinguish, at first sight, which are the profitable and which the unprofitable plots, like the interesting Babylonian landmark or boundary stone marked off the ownership of different plots of ground, and which you can now see in the British Museum. But though scientific research may start with no immediate purpose but its own, yet its hope is progress; its creed, that "knowledge is power"; and its expectation that, without asking how, yet somehow its results will ultimately be beneficial to humanity.

Leslie Stephen, in his introduction to his work on "Utilitarians," has written: "The love of truth in the abstract is one of the weakest influences in human nature. Well! Be it so. Still, "the sacred hunger of science" is keenly felt by many, and in some it would seem to be a necessity laid upon them, like the necessity to preach felt by St. Paul. And just as St. Paul exclaimed, "Yea, woe is unto me if I preach not the Gospel," so these eager investigators would in the same spirit cry out, "Yea, woe is unto us if we make not experiments."

It is by means of experiments which can be planned and controlled at the will of the explorer, and especially by experiments on living animals, that so many of the recent changes have been made in our views of the pathogenesis and diagnosis of disease, particularly of fevers and the infective diseases of wounds, as well as in our methods of treatment.

But I would not have you suppose that I regard research by experiment as of recent or modern date. It is not so, not even research by experiments on animals. Hippocrates was the first to lead medicine in the right track. He employed experiment as well as observation, and thereby succeeded in freeing medicine from the fantastic speculations of the pre-Socratic philosophers. He was, moreover, the fountain source or spring of the flowing stream of medical science, whose course, however, was soon to be checked by the dialectical and rhetorical gyrations in the whirlpool of Greek philosophy, by the pitfalls of Galenic Aristotelianism, the shifting quicksands of Scholasticism, and the deadening and paludal morass of the Middle Ages; but it came bubbling out again as little rivulets into the

No. 4501.

sunshine of the Renaissance, acquired force and volume by the Reformation, and flowed onwards unchecked and in full stream through the smooth and level plains beyond the Revolution; there it is bounded only by the horizon, the clouds and darkness of which are steadily being pierced, dissolved, or made to recede by the penetrating rays of the lime-lights of modern methods of research.

Galen, notwithstanding the obstacles he raised, by his mistaken and misleading worship of Aristotle, to the progress of medicine for a period of nearly 1500 years, nevertheless asserted the importance of anatomy—though, unfortunately, he only knew anatomy through the dissection of animals and not of the human subject; and he was the parent of

experimental physiology.

Towards the middle of the seventeenth century Descartes -some of the most learned philosophers and educationists of their time—resorted to dissection of living dogs and other animals to demonstrate the circulation of the blood; and were accused, possibly as unjustifiably as the scientists of to-day, of being indifferent to the cries of their victims.

In other departments of physical science recourse was had in the past centuries to experiments. Bacon, in his "Natural History," describes the importance of making experiments, and indicates a very large number. Pascal, about the year 1648, made most important and decisive experiments on the weight of air, experiments which, according to Sir John Hershel, "tended more powerfully than anything else which had previously been done in science to confirm in the minds of men that disposition to experimental verification which had scarcely yet" (he was writing in 1830) "taken full and secure root."

Boyle, in the middle of the seventeenth century, instituted exact experiments into the relation between colour and heat, and thereby laid the foundation for the union of optics and thermotics; he also advanced the science of hydrostatics, and established chemistry on a real basis as a science capable of dealing with the organic world. Boyle constantly insisted on two fundamental principles—namely, (1) the importance of individual experiments; and (2) the comparative unimportance of the teaching of antiquity on physical science. He inherited, so to speak, these opinions from Bacon—"First to doubt, then to inquire, and then to discover." Boyle's propensity to doubt is evident throughout his writings, and he gave to his essay on crystals the title . Doubts and Experiments Touching the Curious Figures of Salts.

The determination to subordinate old notions to new inquiries was emphasised in Boyle's lifetime by the incorporation in 1662 of the Royal Society, which was formed with the avowed object of increasing knowledge by direct experiment. According to Dr. Paris ("Life of Sir Humphry Davy") the Charter states that the society was established for the improvement of natural science, and that this epithet natural was introduced in contra-distinction to supernatural, because at that period the arts of witchcraft and divination were very extensively encouraged.

In the eighteenth and nineteenth centuries experimental research was very rich in discoveries. Research by experiment has been enormously advanced and extended by chemistry, photography, the improvement in instruments, and other means. Animal chemistry has been of the greatest assistance to the physiologist and pathologist, as have the microtome to the histologist and embryologist, and the

microscope to the biologist and bacteriologist.

The microscope was essential for experiment as well as for observation. By its aid it was ascertained that the organisation of vegetables is nearly as complicated as that of animals, that there is harmony between the animal and vegetable kingdoms, and a close relationship between the physiology of plants and animals. Without the microscope bacteriology would have been impossible, and some of the greatest developments of scientific research would never have been brought about, except by the help of microscopes of high Though the microscope in its crudest form was invented so long ago as 1590, and was exhibited in London in 1620 by Drebbel, it was only by slow degrees that it reached its present state of perfection. Improvements are still in progress, and only the other day a demonstration of a new invention was given at the Academy of Sciences of Paris. It consists of photography, by kinematograph, of microscopic images obtained by side-lights, which constitutes the ultra-microscope. By this combination of kinematograph, microscope, and side-lights, photographs are obtained showing microbes, so small as to be invisible to the eye under the ordinary illumination and microscope, moving in their natural surroundings. By magnifying, the microbes of sleeping sickness are seen twisting about among the red cells of the blood, and are said to appear as large as eels.

Specialism, in spite of certain definite drawbacks, has unquestionably been another cause of advance in medical science. Medical science, in common with industries and other branches of science, has made remarkable progress in accuracy, as well as in extent of knowledge, through the experience and investigations of those who have specialised

in various departments.

In the past one of the great obstacles to the advance of medicine was the tenacity of unproven hypotheses. experimental methods of research the truth or falsity of hypotheses is tested, in many instances very quickly, before they are either accepted as explanations of symptoms or put into practice in treatment. Experiment is like cross-examinait unravels the essential from the unessential, the relevant from the irrelevant; it insists on direct answer to the question asked. By experiments properly controlled we obtain results on which we can reliably base opinion and form absolute beliefs. This certainty, this absolute belief, is a matter of the utmost importance to us in the practice of our profession. Our object in the treatment of disease is to act, and our desire is to act successfully. And this desire to act successfully is the keynote of all actions; it is one of the ultimate facts of human nature. But human nature, as James FitzJames Stephen states, is so constituted that all actions involve belief, and all successful action involves true belief; and to attain to true belief every source of error must be eliminated, every doubt or uncertainty removed.

In the exercise of our curative science we want our results to be as far as possible *certain*. The conditions necessary for unerring action are first to know what should be done, and second to have the mind to do it. We should like in all cases to be able to say with Hamlet:

"Seems, Madam! Nay, it is. I know not seems."

In respect to many diseases and injuries, the safeguards of experimental research have obtained for us this certainty, and we can put our treatment into practice with the full assurance that we are taking the direction of success, though, even so, of course, we cannot always command success, for the reason that we have to war against disease and death, and death we know is the lot of all:

"All that live must die, Passing through nature to eternity."

But our deservedly high appreciation of experimental research must not dull our sense of the great value of clinical and post-mortem observation. The laboratories are so full of promise, such a land flowing with the milk and honey of prospective discoveries—far off it may be, but yet so rich—that there is some risk that they may monopolise attention. The wards and the post-mortem theatre also yield products, not a few and by no means unimportant or insignificant. The acute and minute observation, quite apart from experiments, of trained clinicians and pathologists has resulted in the discovery of many facts of first-rate importance, and the generalisations therefrom have yielded sound and guiding principles of diagnosis and treatment. Thus have become famous the names of Morgagni and Rokitansky, of Sydenham and Boerhaave, of Watson and Murchison, of Hilton and Paget, of Wilks and Gull, of De Morgan and Charles Moore, and many others.

Percussion and auscultation, the stethoscope and thermometer, the ophthalmoscope, the laryngoscope, and other instruments for illuminating parts and cavities of the body have increased the means and the efficiency of clinical examination and diagnosis.

The importance of developing the faculty of observing cannot be exaggerated. Every medical student, every medical practitioner, can and ought to cultivate it. At all times and in all places it can be exercised; whereas experimental research requires special and often elaborate conditions and equipment. Moreover, we all cannot give

up the time from our particular lines of work which experimental research demands, and not everyone is endowed with the qualifications requisite to pursue it successfully; so that many, the majority in fact, must be content to employ the knowledge acquired by the experimental work of others. Observation, it is true, compared with experiment, is very slow, and is like the crawl of the tortoise in contrast with the strides of the ostrich, but it improves with practice, ripens with age, and the coördination of collective observation increases experience and expedites conclusions.

"Experience is by industry schieved And perfected by the swift course of time."

In my recent "Sir William Mitchell Banks" lecture I showed how the modern operations for cancer of the breast have been established by the careful observations, of clinical phenomena, and of the facts of morbid anatomy, made in this hospital by Moore and De Morgan, and which have been confirmed quite recently by Mr. Handley.

Another illustration of the brilliant results of individual and collective observation is the discovery of the association of myxœdema with the loss of the thyroid gland, thence followed modifications in the operative treatment of the thyroid, and the prevention and cure of myxœdema by the administration of thyroid extract. I am, however, aware that these results connected with the thyroid are sometimes, but unjustly, claimed as a triumph exclusively of experimental research.

The enormous strides made by scientific researches afford reason to expect that the so-called systems of medicine such as those associated with the names of Hoffmann, Brown, Cullen, and others, each of which is based upon the idea of inding an explanation for every form of disease, have vanished for all time.

At the present time, however, quackery is rife in Germany in the form of the "natural" treatment (Naturheilkunde), and in this country and America in the form of Christian Science. We are much indebted to Mr. Stephen Paget for his instructive book and his recent address on Christian Science, but there is one aspect which he has not gone into, and on which it is impossible to speak without trespassing beyond the bounds within which it is usual to limit discussion on medical subjects; yet it is with reference to this aspect that I crave your attention for some minutes. The teaching and practice of Christian Science ignore all the physical reality of sickness set aside all the recognised means of curative science, and rely entirely on an appeal to "the source of life, for more life." Its method is to call on the Divine Spirit by means of concentrated thinking, and by thus drawing upon "spiritual force" to remove an idea of duscase, the disease itself being said to have no actual or real existence.

In theory Christian Science healing differs from Faith healing in this: Faith healers do not doubt the reality of disease and suffering, but believe that the Spiritual and Divine force neutralises and counteracts them; whereas the Christian Scientists deny entirely the existence of a body or of pain and sickness, and profess to call down the Divine influence to overcome a false idea—a misimpression. Like the saints of old, Mrs. Eddy and her followers claim the true source of their cures to be the direct action of God. Such a claim, if not put forward in so many words, is de facto a claim to be able to work miracles, and none the less so because they talk and write in psychological manner of the "power of an idea" and the "annihilation of an illusion." A miracle is defined as a plain and manifest exercise by the agency of man (including prayer and contemplation under the term agency), or by God at the call of man, of those powers which belong only to the Creator and Lord of Nature. I purposely omit from this definition any reference to signality. The reason for considering miracles as signs is based on the Greek word $\sigma \eta \mu \epsilon i \sigma_{\nu}$, of which "miracle" is the ordinary translation, and from which the word semeiology, meaning a knowledge of the signs and symptoms of disease, is derived.

The Christian Scientist cannot get away from the fact that, on his own showing, he thus attempts to work miracles. It is to the purpose therefore to criticise the "cult" from this point of view. The miracles of which we have authentic record are (1) those of the New Testament; (2) those of the Old Testament; and (3) the miracles of the Early Christian Church—the so-called ecclesiastical miracles. The miracles attributed to the Roman Emperor Vespasian

² General View of the Criminal Law of England.

are no doubt pure fabrications and Mahomed's miracles read like sleight of hand and jugglery.

The miracles of the New Testament were performed (a) by Christ himself; (b) by the Apostles; and (c) by the Disciples. There is no difficulty in showing that Christian Science departs in four important particulars from the miracle working described in the New Testament. The points of difference I refer to are that the Christian Scientist (1) requires faith or self-confidence in the patient; (2) attributes therefore insufficient importance to the faith or "mental concentration" of the healer himself or herself; (3) refuses to employ any physical means of treatment; and (4) is unable to perform certain acts which, we are explicitly told, could be done by those who worked miracles under the Christian dispensation.

Many of the New Testament miracles were those of healing; those of the woman cured of an issue of blood, the leper cleansed of his leprosy, and the blind men restored to sight by mere touch, were performed by Christ himself on persons who were told their faith had made them whole; those of the widow's son, Jairus' daughter, and the son of "one of the multitude" seen after the transfiguration, were wrought by Christ through the faith of the parents of the afflicted. The centurion's servant was cured of the palsy through the faith of the centurion, which was said to have been greater than any which had been found even in Israel.

I. In neither of these four last-named cases was there any cooperation on the part of the individuals restored to health. In the performance of the miracles wrought upon them they were purely passive agents. Christian Science, on the other hand, requires an effort of contemplation or mental concentration, of will power, or of faith, on the part of the patient to be cured. She cannot, however, appeal to the New Testament for support of this teaching, for besides the instances of the substitution of the faith of another for that of the person who was the subject of the miracle, there were other miracles in which there was no such substitution. Neither the man blind from his birth, nor the nine lepers, nor the man with the legion of devils, are stated to have exhibited faith by prayer or otherwise before or during the accomplishment of the miracle. Nor did any other person do so on their behalf. In the case of the cripple of Lystra, St. Paul, "steadfastly beholding him and perceiving that he had fail. to be healed," cured him. The cripple had heard Paul speak, but he had made no appeal or sign or personal effort to be healed. St. Peter healed the lame man at the gate of the Temple, cured Eneas of Lydda of the palsy, and restored Dorcas, alias Tabitha of Joppa, to life; but there was no cooperation on the part of those treated. The miracles of Philip and Stephen testify apparently to the same fact, for being "full of faith and power" themselves, they "did great wonders and miracles among the people."

Thus, though Christian Scientists are able to refer in support of their own method of "absent treatment" or healing in absentia to the single instance of the centurion's servant, there are many cases recorded in which there was no cooperation or participation in thought-concentration on the part of the patients themselves. Is it not therefore effrontery on their part to ascribe their failures to the patients' defective capability of thinking, or deficient force of will,

or want of faith?

Il. In the cures which were wrought by the Apostles and Disciples the faith of the active agent (i.e., the Apostle or Disciple) was of primary importance—in fact an essential factor for the healing. When an explanation was sought of the failure of the Disciples to cure the epileptic and lunatic boy, the reply was, their unbelief. On the other hand, the 70 disciples who were sent, two and two, into every city and place, were believers. They returned from their journeyings with joy, proclaiming "Even the devils are subject unto us through thy name." Further, there is the reply to the Apostles about the grain of mustard seed and the sycamine tree, when they asked "Increase our faith." Is not the correct argument from analogy, therefore, that when the Christian Scientists fail it is on account of their own deficiencies-of their own lack of power ?

III. Nor can they justify by New Testament teaching their own rejection of every kind of physical aid in their treatment of the sick. In the case of the man blind from his birth. Christ made clay with his spittle, and after anointing the eyes of the blind man with the clay, sent him to wash in the pool of Siloam. Repeated stress is, in the narrative, laid on

the clay and the washing. Again, we are told "God wrought special miracles by the hand of l'aul, so that from his body were brought unto the sick handkerchiefs or aprons, and the diseases departed from them, and the evil spirits went out of them.

IV. It has been held that the power of working miracles was transmitted to the Apostles and Disciples in such a manner that it came necessarily to an end on the death of the last of the Apostles.3 If they dispute this, are the Christian Scientists prepared to base their self-confidence as healers on the only passage in the Bible which it is said gives any support to the idea that miracles are in these days performed, and have been possible throughout all the ages of the Christian Church? The passage is, "And these signs shall follow them that believe. In my name shall they cast out devils; they shall speak with new tongues; they shall take up serpents; and if they drink any deadly thing it shall not hurt them; and they shall lay hands on the sick, and they shall recover."4

If the laying on of hands is part of the healing, how do the Christian Scientists justify their attempts on patients at a distance! And why do they restrict themselves to the exercise of the healing power only, and disregard all the other endowments specified in the text? Do they speak with new tongues? Could they take up serpents or drink deadly things and yet remain unharmed? Would they take, say, concentrated laurel-water instead of claret for dinner, or eat aconite root instead of horse-radish with roast beef? Why do they not give demonstrations in their churches or temples of the impunity with which they can manipulate venomous snakes and serpents ?

When St. Paul, after escaping drowning from shipwreck, was being kindly entertained by the inhabitants of Malta, a viper came out of a bundle of sticks and clung to his hand. The people at once supposed he was a murderer, and that vengeance had overtaken him in spite of his escape from the sea. But when he shook the beast off into the fire and suffered no harm the people changed their minds and thought he was a god. Why do not the Christian Scientists increase the evidences of their power, and improve the estimation in which they are held, by showing in the manner of St. Paul how unmerited are the imputations of manslaughter against them ?

It was foretold that sorcerers and false prophets would arise who would declare signs and wonders, insomuch that if it were possible they would deceive the very elect. Was Christian Science included in this anticipation? When in 56 A.D. the seven sons of Sceva, the Jew of Ephesus, and other "vagabond Jews and exorcists" made trial of their power of healing, the evil spirit answered them by saying, "Jesus I know, and Paul I know, but who are ye?" And then the man in whom the evil spirit was leaped on Sceva's sons and overcame them, and prevailed against them so that "they fled out of the house naked and wounded." There are, not a few, persons who, knowing the fatal consequences attending the practice of the Christian Scientists would witness without disturbance to their bowels of compassion the advent of a spirit which would chastise those presumptuous persons as Sceva's sons were treated.

The Pharaoh of 3400 years ago called together the wise men, the sorcerers and the magicians of Egypt, to practise their enchantments and to cast down every man his rod, and they became serpents. But the rod of Aaron swallowed up the rods of all of them. Would it be altogether a misfortune if modern science or public spirit, or both, like Aaron's rod,

would swallow up the disciples of Mrs. Eddy?

It was commanded in old time to forbid no man to do miracles in the name of the Master, nor would we quarrel with the Christian Scientists for trying their minds on miracles if they did no harm to others thereby. Our repugnance to their presumption is because they mislead the credulous, the ignorant, and the helpless into supposing that miracles will be wrought at their instigation, and thereby persuade, if they do not indeed enforce, their victims to neglect every physical means for their recovery. We are not concerned as medical men with the metaphysics of Christian Science. What we resent is the effect of their teaching and practice in cases of organic and infective diseases, and in severe surgical injuries. It is because of their meddling with medicine, not their muddling with

metaphysics, that our profession, in the interest of sufferers and in the interest also of the general public, opposes their false doctrine and cries out against their cruel and fatal

The miracles of the Old Testament formed part of the Theocratic government of the Jews, and were wrought for the purpose of impressing an ignorant and semi-barbarous people with the idea of the power of the Deity. To us the striking feature about many of them is the thinness of their veil of the marvellous. As miracles they seem beggared of the miraculous. They were, however, quite sufficient to terrify and excite the wonder of a semi-civilised race whose simple rudiments of learning made them as "children" in the condition of "slaves." For instance, Samuel called to the Deity for thunder and rain during wheat harvest so that the people might realise their wickedness; and the thunder and the rain came. This brings back to my thoughts a circumstance related, I think, in "She," or some other book by Rider Haggard. Some one, knowing that an eclipse of the sun was due on a particular date, saved himself from being put to death by publicly foretelling the approaching darkness, and thus leading the natives to fear him as a god or a prophet. There are many nowadays who foretell, like Samuel, what the weather is going to be; such predictions are a part of the news supplied to us by the daily and weekly press. Besides, we offer prayers in churches still for sunshine or showers, and sometimes the rain or the fine weather as the case may be comes as a post hoc, if not as a propter hoc.

Then there is the cure of King Hezekiah, who was "sick unto death" from the effects of a boil, but whose life was saved by his own tears and prayers and through Isaiah, who prescribed "a lump of figs" to be applied to the boil. No one in these days, however, would think it wonderful that a fig poultice should bring away the core of a ripe boil in three days.

There is little to venerate or respect in the miracles of the saints of the second, third, and fourth centuries. miracle associated with the career of St. Ambrose in the fourth century looks like imposture and gullibility. At a time when his influence was on the wane and required vigorous support St. Ambrose had a dream, which led to finding beneath the pavement of the church the remains of two martyrs. The common people crowded to see these venerable relics, and many who were sick were healed by touching the bones. St. Ambrose was in ecstasies over these miraculous cures, and preached eloquent sermons thereon. This was but a poor and vulgar imitation, however, of the miracle of the man who, when about to be buried, was thrown into the sepulchre of Elisha, and came to life immediately his body touched the bones of the prophet.

The tactics of St. Ambrose remind us of the miraculous cures which were worked on the fanatics at the tomb of the Jansenist deacon, François de Paris (Abbé de Paris), in 1730; they also recall the procession of the multitudes one has seen at Lourdes; and the filthy fragments of dressing and the discarded sticks and crutches ostentatiously thrown into the hedgerows near the shrine of miraculous cures, in the South of Ireland. The cemetery of St. Médard in Paris where François was buried became so overrun with pilgrims that the place of the grave was walled up; hence arose the satirical epigram: "De par le Roi defense à Dieu de faire miracle en ce lieu."

All the Ecclesiastical miracles are highly improbable. They resemble those fictitious legends, those mists of error, which have been invented by the imagination of impostors for acceptance by the credulous, to some of which I will in a moment refer.

In B.C. 280 there arose in Alexandria a medical sect known as the "Empirical School." Its members relied solely on tradition, analogy, and individual experience, and rejected all philosophical theories, and all a priori reasoning. The term "empiric" in the present day is sometimes given to quacks-i.e., those who practise medicine or surgery, but who have not received a regular medical training. commonly it is the name applied to qualified men, who rely on tradition and personal experience. By such, anatomy and physiology are considered to have but little connexion with practice, the whole object of the art and science of medicine in their view being to obtain practical results by therapeutical agents, to search out specifics for every malady, and to cure disease without troubling to discover its true pathology and pathogenesis. It was empiricism of this kind which laid our

profession so much open to the charge of charlatanry, and was one of the reasons why it excited the scorn and satire of such men as Petrarch, Montaigne, and Molière.

Empiricism has had its professors in all countries and in all ages since the days of the Alexandrian School. Suctonius relates that the life of Augustus Cæsar was saved by the physician Antonius Musa, who insisted that hot medicines, in his experience, were the only remedies for the disease from which Cæsar was suffering; all the rest of his doctors had thought the same about cold medicines. Herodotus tells that the Lybians professed that persons were prevented from having catarrh for the rest of their lives if the veins of the head and temples had been burned and cauterised when they were four years old. Galen reported a case to prove that leprosy was cured by wine drunk out of a vessel into which a viper had crawled.

Montaigne, the earliest systematic sceptical writer in the French language, published at the end of the sixteenth century an amusing but satirical essay on physic and physicians. He mentions many of the empirical remedies then in use, such as "the left foot of a tortoise, the urine of a lizard, the dung of an elephant, the liver of a mole, and blood drawn from under the right wing of a white pigeon. Montaigne comments at some length on his own sufferings from stone in the bladder. He avoided being treated by physicians, and no wonder, for he adds, "and for us who have the stone, so scornfully do they use us in our miseries" that they prescribe "the excrements of rats beaten into a powder." He learnt the fallacy of the idea that the blood of a he-goat was a remedy for stone by having one killed and finding stones within its body. From Montaigne's own account, however, it is clear they were not urinary calculi but bezoars, which are not uncommon in the stomachs of goats, antelopes, and other animals, and which formerly were esteemed as antidotes to all poisons.

Montaigne illustrates what he describes as "the variety and weakness of the rationale of the profession," by citing the reasons given by one set of physicians why aperitive medicines are proper for persons subject to the stone, and the reasons given by another set why aperitive medicines are dangerous to those same persons, by tending "to create gravel, and to occasion a certain and most painful death." Here in this hospital public opinion has required us to try numerous purely empirical drugs for cancer, such as chian turpentine, condurango root, violet leaves, molasses, and others-all as entirely without curative effect as the repulsive

things mentioned by Montaigne.

Under Arabian and other Oriental influences medicine became mixed up with magic, alchemy, and astrology; and in the Middle Ages it came under the yoke of theological dogma, and was enslaved by superstition. The influence of superstition continued long, and, though scotched, is not even yet killed. The practice of touching as a cure for scorbutic diseases was exercised by all our Sovereigns from Edward the Confessor to the time of Queen Anne, and was especially prevalent in the reign of Charles II. Though it is unfair to the memory of the illustrious physician of Norwich, Sir Thomas Browne, to quote him in illustration of the superstitions which prevailed in his day, without mentioning that in a subsequent work published 12 years later he deliberately attacked them as "Vulgar and Common Errors," it is nevertheless true that in "Religio Medici," published in 1634, he declared his belief in the philosopher's stone, in witches, in palmistry, and in spirits and tutelary angels; and he rated those who denied the existence of witches as atheists and "worse than infidels."

A custom called "La Couvade" formerly prevailed in the south-west part of France, and very widely, too, in other parts of the world, which obliged the husband of a lying-in woman to go to bed and take charge of the baby. he who received the congratulations of his friends, in bed; whilst the mother got up and went about her business in the house, as if nothing had happened. Remains of this custom are said to exist among different races even at the present day-namely, in Corsica, Guiana, Borneo, and elsewhere. The explanation used to be that the father had to expiate original sin; but of late it has been held that he was put to bed to be out of the way for fear that, if he were going about as usual, by some unintentional act he might injure the baby, not physically, but through the spirit.

It was at one time taken for granted in Christian countries, and the view is said to have been sanctioned by Luther, that hail and wind were the works of wizards. Combe, in his "Constitution of Man," relates that in the middle of the eighteenth century the country west of Edinburgh was so unhealthy that every spring the farmers and their servants were seized with fever and ague, and that these visitations were believed to be sent by Providence. After a while the land was drained and the fever and ague disappeared.

Swinburne, in his "Travels through Spain (1775-1776)," tells that the clergy in the latter part of the eighteenth century were on the point of putting an end to the opera because they attributed the want of rain to the influence of that ungodly entertainment.

In 1760 the physicians of Madrid opposed the cleansing of the streets of the city, as they considered the smells emitted from them were wholesome. The argument was that "the air being sharp and piercing it was extremely probable that bad smells made the atmosphere heavy, and in that way deprived it of some of its injurious properties." But Spain was a particularly backward country, for Townsend during his journey through Spain in 1792 found that the leading physician of the country doubted the truth of the circulation of the blood, which Harvey had proved 150 years before. Even in the beginning of the nineteenth century there was not a lecture room for practical instruction in the colleges of either Madrid, Barcelona, or Cadiz.

As long as it was forbidden to question the teaching of the Church physical science made but slow progress, solentific investigation was under great restraint, and scientific investigators were frequently punished as heretics. As long as periodic attacks of fever and ague were believed to be visitations sent by God it was heresy to make efforts to prevent them. As long as a lengthy period of drought was regarded as a Divine punishment for indulgence in ungodly amusements it was conceivable that the closure of the theatres and opera houses might bring down the gentle rain from heaven as well as the drop curtain of the stage. But as soon as fever and ague disappeared with effectual drainage, it was possible to realise that the cause of these diseases was the stagnant state of the land, and not the vengeance of an offended Deity. And when the rainfall. which at one time makes the corn grow, and at another ruins the crops before they can be garnered up by the farmer, is ascertained to be a necessary consequence of other antecedent occurrences, and its variations are brought under known laws of Nature, then probably the prayer for rain will be expunged from our Prayer Books and Church Services.

In 1853 a severe epidemic of cholera spread over this country and was very destructive in Scotland. The clergy. supported by the people of Scotland, applied to the Home Secretary to know if the Queen would appoint a day for a national fast, which was the most effectual way in their judgmen of propitiating the Deity to stay such a terrible pestilence. This view was in accord with the superstitious fancies as to the origin of disease then prevalent in Scotland, and which were once almost universally cherished alike by Pagans, Catholics, Protestants, and Presbyterians throughout the world. Lord Palmerston, the Home Secretary at the time, had the courage to set at defiance such narrow notions. On behalf of the English Government he informed the Presbytery of Edinburgh "that the affairs of this world are regulated by natural laws, on the observance or neglect of which the weal or woe of mankind depends," and he advised that it was better to cleanse than to fast, and that under the circumstances activity was preferable to humility. He urged that efforts should be made to destroy the causes of disease by improving the dwellings and other conditions of the poor. If this were done he doubted not that all would go well, otherwise pestilence would be sure to revisit them, "in spite of all the prayers and fastings of a united but inactive nation." The action of Lord Palmerston showed the triumph of common sense over prejudice; of practical wisdom over ignorant helplessness; of science over the old theological, as distinct from religious spirit, which formerly made martyrs of scientific men by persecution and sometimes by death.

In the half-century which has elapsed since the correspondence just referred to between a member of the British Government and the heads of the Scottish Presbyterian Church, science has made a progress unparalleled in any previous period. At that date the continued fevers, and

diphtheria, erysipelas, pyæmia, septicæmia, and other septic diseases were ever present mysteries. Their immediate causes were unknown, their treatment tentative and uncertain, their prophylaxis of the most general and miscellaneous character. To-day all is changed. The cause of cholera is sought for amongst the microbes, and the majority of infective diseases have been proved to be due to the invasion by specific organisms, which come from without and multiply within the body. Prevention and treatment, immunity and cure, have been, thanks to experiment, placed upon a definite and sure foundation. The very microbes which cause the disease are utilised, directly or indirectly, as the means of protection against and palliation of it.

But although the irrational opinions formerly entertained in regard to the origin of disease in particular, and to the phenomena of nature in general, are well-nigh extinct. and although the views of science and of religion (as distinct from the theological view) are well in accord as to the uniformity and order of the material world, differences still arise in reference to the complex nature of man and the relation of the mental and the material parts of him. It is too much to expect that all opposition to science and research have ceased and that superstition is got rid of altogether.

Though the struggle between theology and science is probably over and plague and pestilence, as well as earthquakes and famine, are now universally admitted to be the natural effects of other antecedent material events, research by experiment is at the present time being hotly resisted by a band of no doubt well-meaning persons whose intentions are good but whose methods are tortuous. This band having, by way of exciting prejudice, stigmatised experiments on living animals with the name of vivisectionas though all instead of a mere fraction of a unit per cent. of them were cutting experiments—has, under the assumed banner of humanity, moved a great charitable fund for the benefit of the sick poor to exclude from its bounty any direct or indirect assistance to medical education or research, and has been the cause of the appointment of a Royal Commission on Vivisection, whose report we are at this moment eagerly awaiting, though without fear or misgiving as to the

Within the last few days 7 we have read (to quote the words of Lord Curzon's letter to the Times on Nov. 4th) of an "alleged interview between a notoriously hysterical journalist and the spirit of the illustrious departed, to which publicity has been given," as a political manœuvre in favour of an unpopular Budget. We have had at the same time the opportunity of following a trial of, and a verdict with damages of £1000 against, a hypnotist, in support of whom persons were found to bear witness to his marvellous cures and to his indifference to the dangers of the "Cage of Death." The judgment of Mr. Justice Darling on this case deserves careful perusal. There is also to be seen in the latest issue of a journal whose statements carry much weight with many of its numerous readers the following extraordinary editorial admission: "We have no difficulty in believing that ulcers that have a malignant aspect may be healed by the hope that comes from a potent suggestion. have ourselves known of more than one case in which every clinical sign of malignant disease of the stomach was present, and in which a cure was effected by means that could only have derived their potency from suggestion.

One of the results of "looking back" is that we realise how phases of opinion and cycles of thought, as well as epidemics of disease, are prone to recur. It is possible for the oldest amongst us to recall periods at which mesmerism, bypnotism, thought-reading, table-turning, and faith-healing were temporarily in vogue, and then passed away again out of favour or notice. Just now there is a phase of opinion—entertained, too, by some honourable and distinguished men—that there is scope and reason for the exercise of "Suggestion" as a remedial and curative agent; and it has been seriously put forward that the already vastly overburdened medical curriculum should be still further charged by the addition of "a sound psychological training." so that every medical practitioner shall be able to

⁷ It is well known that the number 13 is omitted in the enumeration of cabins on board ship and of rooms in hotels; but an astonishing instance of present day superstition is Lord Crewe's statement in the House of Lords that an alteration was made in the Irish Land Bill "in order to change the number of the Congested Districts Board from 13, which was regarded as unlucky." (Observer, Nov. 28th.)

employ "mental therapeutics" and to engage in "the scientific practice of suggestion."

Surely it behoves the leaders of medical thought and opinion to walk most warily in this direction. A committee to make a careful scientific investigation of the nature and subsequent history of the cases asserted to have been cured by Christian Science, by hypnotism, and at Lourdes, might make a valuable contribution as to the questions involved; but I venture to think it would be highly undesirable to combine "the practice of suggestion" with the ordinary practice of our profession. Such a course seems to offer encouragement to those outside the profession to make arrogant pretensions to curative powers, and might possibly lead to unfounded accusations and regrettable indiscretions even within the profession itself, especially if the character of the cases which are regarded as proper subjects for this treatment be remembered. Even if it should come to be decided that a set of persons should be properly trained to practise treatment by suggestion, I am not quite sure that the doctor should have more to do with the treatment than merely to examine and pronounce whether the case is suitable for its employment.

I will conclude by repeating what I have previously said in the course of this address, namely, that all actions involve belief, and all successful action true belief, and that to arrive at true belief in medicine we must go through scientific scepticism to knowledge, through doubt to certainty, and replace empiricism by experiment and superstition by research.

A FURTHER CONTRIBUTION TO THE SURGICAL TREATMENT OF PUERPERAL PYÆMIA.

BY ERNST MICHELS, F.R.C.S. ENG., SURGEON TO THE GERMAN HOSPITAL.

In 1903 I reported a case of severe puerperal pyæmia in which, following Trendelenburg's suggestion and example, I tied the left ovarian vein, preventing in this way the further propagation of the septic process and obtained a rapid and complete recovery in an apparently hopeless case. Since that time I have had two more cases of this kind under my care and will report them quite shortly.

CASE 1.—The patient, who was 23 years of age, was admitted into the German Hospital on Oct. 25th, 1908. She had been confined on Oct. 11th; two days later she began to feel ill, and on the third day she had a severe rigor. rigors recurred very frequently; treatment by intra-uterine douches brought no improvement. On admission the temperature was 105° K., the pulse was very rapid, and the patient was very ill and slightly delirious. The uterus was soft and very little enlarged, and the os was permeable; there were no discharge, no laceration, and no swelling in either broad ligament. The abdomen was soft; there was no rigidity, no distension, no vomiting, in fact no sign of peritoneal irritation. Some shreds of placental tissue were removed from the uterus, and its cavity was washed out with lysol; after this the temperature came down to 100°. On the following days, however, severe rigors recurred, during which the temperature rose to 106.40 and 107°, and even in the interval between the rigors the patient was very seriously ill. I had no doubt in my mind that this was not an infection of the purely pyemic type, and that general septicæmia was largely responsible for the condition. But bearing in mind the result of my first case I thought it right to prevent as far as possible the further entrance of septic matter into the circulation. On Oct. 29th (18 days after delivery), under spinal anæsthesia, the patient having had an injection of scopomorphine first, the abdomen was opened in the middle line. There was no peritonitis; the left ovarian vein was felt as a thick cord completely blocked by a soft thrombus rising from the broad ligament. Its peritoneal covering was divided and the ligature was applied as high as possible, but I was doubtful whether it was really placed above the central end of the thrombosis. The right ovarian vein-which was also thrombosed, although to a much smaller extent-was treated in the same way. From a small incision through the posterior peritoneum in the middle line the two internal iliac veins were exposed but, as

they did not show any signs of disease, were not isolated or Of the further course of the case I have only to state that the operation failed to bring about the desired relief. For a short time the patient was distinctly better, but soon she began to complain of pain in the right knee and in the left elbow. On Oct 31st she had a fresh rigor. Undoubtedly septic matter continued to enter into the circulation, and, as I attributed this to the ligature of the left ovarian vein having been placed too low down, I exposed the vein once more by a retroperi-toneal incision, isolated it with great difficulty from the ureter, the parts being all matted together and almost indistinguishable, and placed another ligature just below the termination of the vein. This ligature, however, cut through, and pus escaped from the central end, but no blood. There could be no doubt that the infection had spread beyond the reach of practical surgical measures. Within the next few days the signs of severe septicæmia and pyæmia increased markedly; the right knee-joint was found to be full of pus and had to be opened (Nov. 3rd); from Nov. 5th rigors recurred every day, and the patient died on the 12th, 32 days after her confinement. The necropsy showed the large glandular organs in a state of fatty degeneration; some of the inguinal and iliac lymphatic glands were suppurating. The right ovarian vein was occluded above and below the ligature by a healthy thrombus; the two internal iliac veins were free from thrombosis and quite patent. The case presented undoubtedly some of the worst features of puerperal infection; in addition to the pyæmia there were also obviously signs of septicemia.

CASE 2.—The next case was more satisfactory. patient, who was 38 years of age, had had six children. The history of her last pregnancy remained somewhat obscure, as for some reason details were concealed from us as far as possible, but we were able to ascertain that there had been an early abortion on April 5th or 7th, 1909, hæmorrhage continued until April 10th, and from that date daily recurring rigors set in. The patient was admitted on April 15th, with a temperature of 99° F. and a pulse-rate of 72. She looked very ill and anæmic. The uterus was only slightly enlarged, and at its right side, filling up the right broad ligament, was a hard swelling of the size of a small apple, immoveable and very tender. A few hours after admission a severe rigor occurred, the temperature rising to 104.60 and the pulse to 124. This being the fifth or sixth rigor since the commencement of the illness, it was decided to lose no time, and on the following day the abdomen was opened. The right broad ligament was found distended by large coils of thrombosed veins; laterally the thrombus extended well up behind the peritoneum along the interior of the ovarian vein. The peritoneum over the ovarian vein was incised; the vein was ligatured some distance above the thrombus and its peripheral end was excised, together with the whole of the right broad ligament and its venous plexus. This part of the operation caused considerable difficulty, as the tissues were very friable, so that all ligatures cut through, and to stop the continuous oozing from the lateral wall of the uterus and from the floor of the pelvis I had to amputate the uterus. The left ovarian and the two internal iliac veins were healthy and required no ligature. A small strip of gauze was placed into Douglas's pouch and another over the central stump of the ovarian vein. The abdominal wound was closed in the ordinary way. The patient made an excellent recovery. The temperature for three days remained between 99° and 101 2°, but no rigors occurred, and from the fourth day the pulse and the temperature were The wound healed by first intention, and the normal. patient left the hospital well and strong on May 15th.

When I reported my first case only very few instances of this operation had been recorded, and the number of successful cases was lamentably small. Only one patient besides my own case had been saved by the operation. In the course of the last few years, however, by the work of several surgeons, some more experience has been gained, and the operation appears in a more favourable light. Bumm, in Berlin, has had fairly good results, and is now a strong advocate of the principle of the operation—viz., the localisation of the septic process by ligature of the great venous trunks coming from the pelvis. Among English-speaking surgeons Cuff, Bland-Sutton, Lendon and Moore in Australia, and chiefly Dr. Whitridge Williams have performed the operation, and

have recommended this form of treatment. Altogether I have been able to collect 64 cases (including my own 3), in which one or several of the large pelvic veins were tied for puerperal pyæmia, and of these 64 patients 29 were saved. This means a mortality of 55 per cent., but, the numbers being so small, I do not think much will be gained by grouping the cases after statistical principles, particularly as we have to do with an illness of which hardly two cases are alike. To form an opinion of the value of the operation one has to study the individual cases, and one may obtain in this way some guiding rules in what class of cases the operation might be undertaken with some chance of success, and how it should be done.

We ought, of course, first to ascertain what is the mortality in cases of puerperal pyæmia not treated by operation. found it extremely difficult to obtain a satisfactory answer to this question. In most statistical tables no sharp distinction is made between deaths from puerperal pyæmia and from other kinds of puerperal sepsis, and one has to rely to some extent on the personal impressions of those who have watched a fair number of these cases, and these impressions are somewhat contradictory. While Bumm places the mortality at more than 80 per cent., Olshausen thinks this an exaggerated estimate, and estimates a mortality of about 55 per cent. There is, however, a general consensus that the disease, although often very protracted, is a very fatal one, and one in which recoveries are rare, and that all forms of treatment hitherto at our disposal are disappointing. mortality of 66 per cent. is, in my opinion, certainly not too low an estimate, and this corresponds with Whitridge Williams's view.

Which class of cases, then, should be selected for surgical interference! All those who have studied the subject agree that in the very acute cases of puerperal pyæmia the chances of success are exceedingly small; in these cases which are due to infection by a particularly virulent type of streptococcus the infection is not propagated along the venous system only; the coats of the veins are quickly pervaded by the cocci and infection spreads along the lymphatic vessels and within the great serous cavities, so that a ligature of the venous trunks can shut off only a very small proportion of infectious matter. On the other hand, Bardeleben has shown by a very interesting series of experiments that if the veins are entered by streptococci of somewhat attenuated virulence, the vascular wall, particularly the endothelium. offers a powerful resistance to the cocci; they are unable to penetrate through the walls of the veins, and their only way of spreading lies within the lumen of the vessels. It is in this class of infection by an attenuated virus that ligature of the infected vessel has its best chance. If by ligature and division of the vessel the cocci are prevented from migrating further they succumb to the resisting powers of the endothelium and of the leucocytes. Clinically it may not be quite easy to distinguish between these two types of infection, at all events in the commencement of the illness. Where the clinical signs of septicæmia prevail and the rigors, which are so prominent and occasionally for some time the only symptom in puerperal pyæmia, are hardly more than a temporary accentuation of the morbid condition, the chance of localising the process by ligature of the veins is very small; on the other hand, patients whose condition in the intervals between the rigors is satisfactory, whose pulse remains good, should have the operation done without much delay. In these cases the decision to operate is often facilitated by the appearance close to the side of the uterus of a hard, tender swelling, formed by the thrombosed veins; it indicates a more or less localised lesion, and, at all events, gives a clue on which side the operation would have to be done.

When Trendelenburg originated this method of treatment he chose the retroperitoneal route to reach the thrombosed veins and in my first case I followed his teaching. I was agreeably surprised to find the operation technically a comparatively easy one; there was no difficulty whatever in exposing the internal iliac and the ovarian vein and to isolate the latter from the ureter; but the conditions were very different in my second case, when, not satisfied with my transperitoneal ligature, I tried to expose the ovarian vein behind the peritoneum close to its opening into the renal vein. On that occasion I found the parts all matted together and very difficult to distinguish one from another. Other surgeons

have found the same difficulty, have even failed to find the trunk of the ovarian vein, and have had the misfortune to injure the ureter, and it seems that in the majority of cases the retroperitoneal operation is more difficult and dangerous than the transperitoneal method. Moreover, the retroperitoneal operation gives access only to one side, and in some cases would have to be done bilaterally. The transperitoneal operation offers the one great advantage: that the extent and the localisation of the disease can be made out at once; with the patient in Trendelenburg's position, the broad ligaments, and emerging from them the ovarian veins, may be identified and dealt with without any difficulty, and a small incision into the parietal peritoneum of the posterior abdominal wall will expose the internal iliac veins. These latter, however, if thrombosed, and in the presence of some periphlebitis, may require a great deal of careful dissection before the ligature can be passed round. A case has been recorded (Haeckel) in which it was found impossible to isolate the internal iliac, and the ligature had to be placed on the common iliac vein. The case was not successful, but the nutrition of the leg did not suffer, and Bumm thinks it permissible to tie the common iliac vein in cases in which the thrombus extends very high up into the internal iliac. Bardeleben, in a successful case, was unable to isolate the vein from the artery, and had to include the artery in the ligature without any untoward results. These two modifications may sometimes be preferable to prolonged attempts at isolating the internal iliac vein.

Theoretically it would seem advisable to tie all four great pelvic veins, the two internal iliac and the two ovarian—and also a very frequently found median iliac vein—so as to exclude all possible channels for the spread of infection. But a fair proportion of cases have been recorded in which, after ligature of two or even of only one of the pelvic veins, a good result was obtained. It is the great advantage of the transperitoneal operation that all four veins can be completely exposed and examined, but it seems sufficient if the ligature is applied to those which are actually diseased, particularly in cases which could not stand prolonged dissection, and they will be the majority. The ovarian veins should be ligatured as near as possible to their point of termination.

Latzko in Vienna has tried several times, and once with success, to approach the diseased veins by the vaginal route. It is impossible to withhold one's admiration for the great skill and dexterity with which this must have been done, but I believe very few surgeons will be inclined to follow his example. View and space are necessarily limited and haemorrhage or any other complication could be controlled only with great difficulty.

Ligature of the veins, or, better still, double ligature and division has proved sufficient in most of the successful cases, but it may well be questioned whether the results could not be improved by excision of the diseased vessels or, in cases where, for some reasons, the retroperitoneal route is chosen, by slitting them open and evacuating their septic contents. In my two successful cases I acted in this way, and I cannot help thinking that the unexpectedly rapid recovery was due to this more radical procedure. Prochownik in Hamburg operated in the same manner and had a very satisfactory result, marred only by a septic infection of the abdominal wall. I admit there is a certain amount of danger attached to this method; the peritoneum may be infected, or the hæmorrhage may be considerable and may necessitate, as in my third case, removal of the uterus. But it is undoubtedly in accordance with our general surgical principles to remove the septic focus wherever and whenever possible. Some further experience is required to show whether this extended operation is really advisable. I would advise in such a case drainage of the abdominal wound. Several otherwise successful cases have been retarded in their convalescence by septic infection of the abdominal wall. The loose flaccid layers of the abdominal wall after pregnancy seem to be particularly favourable to the spread of infection, and the small precaution of drainage is likely to be well repaid.

That there is a certain amount of danger in the operation cannot be denied. In the transperitoneal operation the possibility of a general peritoneal infection ought to be borne in mind, but we should be able to guard against this just as we are able to protect the peritoneum in operations for a gangrenous appendix. It has also been said, and with

justification, that patients suffering from puerperal pyremia are bad subjects for any operation; if we decide to operate earlier this argument is likely to become less important.

It is naturally with some diffidence that one recommends an operation which so far in 55 per cent. of the cases has been unsuccessful, but I would appeal to anyone who will take the trouble to study the individual history of those cases who recovered after the operation. They were all very seriously ill and seemed to be going down-hill rapidly, and I believe I am not saying too much if I state my opinion that the very great majority of them would have died without surgical interference. And among the many failures we find the very first operations which were done tentatively and hesitatingly -often after too long a hesitation. Moreover, a good many cases are included in the list in which, from the nature of the infection, a good result could not possibly be anticipated. By making a careful selection of cases suitable for the operation and by operating at an early stage much could be done to reduce the mortality. Dr. Whitridge Williams has lost only one patient among his five operations, and thinks that in future the mortality should not exceed 10 per cent., at least in cases where thrombosis is limited to the ovarian veins.

It is evident that this form of treatment is still on its trial and that many questions remain which will only be answered by a much more extensive experience, but I think the following may be suggested as a good working rule for the present. 1. In cases of puerperal pyæmia an attempt should be made to localise the septic process by ligature of the great pelvic veins (ovarian and internal iliac and possibly median iliac). 2. The very acute cases of puerperal pyzemia are not suitable for this operation, but the more chronic cases which are due to infection by an attenuated virus promise a good success, provided the operation is not delayed too long. 3. The veins should be exposed by the transperitoneal route in preference to the retroperitoneal or vaginal way. 4. All the four great venous trunks should be exposed and examined, but isolation and ligature seem necessary only for those veins which are actually found diseased. 5. Further experience is required to decide whether the results can be improved by excision of the venous trunks and plexuses in preference to simple ligature.

the venous trunks and plexuses in preference to simple ligature.

HUNTERIAN SOCIETY.—The last day for sending in essays for the silver medal of this society will be Dec. 31st. The medal is awarded for the best essay embodying the results of original observations by a general practitioner.

THE TREATMENT OF NÆVI AND OTHER CUTANEOUS LESIONS BY ELECTRO-LYSIS, CAUTERY, AND REFRIGERATION.¹

By EDWARD REGINALD MORTON, M.D., C.M. Trin. Tor., F.R.C.S. Edin.,

VICE-PRESIDENT OF THE ELECTRO-THERAPEUTICAL SECTION OF THE ROYAL SOCIETY OF MEDICINE; LECTURER ON RADIOLOGY AT THE WEST LONDON POST-GRADUATE COLLEGE, ETC.

Ever since I took charge of the electrical department of the London Hospital the treatment of nævi has been a very important feature of the work, and the number of cases to be treated has steadily and rapidly increased. In a period of six years some 2000 cases have been treated by myself, and during that period the methods employed were electrolysis, puncture with a fine galvano-cautery, and the high-frequency spark. In one case, involving the left mamma of a female child, I used pieces of sterilised magnesium ribbon plunged into the growth and left there. I hoped by this method to avoid destroying the mammary gland, and so far as one could judge the result was satisfactory; but, of course, it is impossible to be sure of this until the child reaches puberty. I am convinced that this method of treating næveid growths has a definite value, but I am also of the opinion that for routine hospital practice it is not suitable.

Electrolysis. - While I used this agent very freely at first, latterly I have reserved it for the cavernous type of nævus, for which I find it the most satisfactory of all that have been proposed. While excision is an ideal method from a theoretical point of view, I am sure surgeons will admit that the method is frequently followed by recurrence—at least I often have cases referred to me for electrolysis in which this has followed excision of the original growth. Possibly also surgeons have had to excise a recurrence following an electrolysis by myself, but if so, they have been polite enough not to tell me of it. In this, as indeed in all methods of treating nævi, the secret of success is to know when tostop. It is better to do less than enough and to finish on a subsequent occasion than to risk an unsightly scar through trying to make one operation do all that may be necessary. It is, no doubt, good policy, even advisable under certain conditions, to make one operation suffice, but when this is done, even with the greatest care, there is no little risk of the resulting scar being less elastic and more noticeable. On the other hand, by adopting a less vigorous plan of campaign and giving full time between the operations for the effects of each to be developed, I have had the most satisfactory results in cases of such severity that the outlook seemed wellnigh hopeless.

One case in particular—a deep, cavernous nævus, involving the left side of the face from orbit to chin-was treated by electrolysis, piecemeal, for nearly two years, during which period the child was anæsthetised no less than 16 times. The result was better than I dared to expect. The face was very nearly symmetrical, and while the affected side was mostly scar-tissue it was soft, pliable, and elastic; every trace of nævoid tissue had disappeared, so far as one could tell. For this method of treatment I always use the bi-polar needle designed by Dr. Lewis Jones. Mine has fairly stout platinum needles, which are heated to redness in the bunsen flame before and after each insertion. They are allowed to cool before being pushed in, except when dealing with scartissue, which is usually very resistant. Here much time is saved if they are inserted while still hot. I have never seen any bad results from this, and what would be a matter of considerable difficulty otherwise becomes quite easy.

I generally use a potential of 10 volts, corresponding to six or eight Leclanché cells, and this is turned on to the needles before the latter are placed in position, the skin itself forming an excellent rheostat.

Cautery puncture.—In my experience the majority of cases can be satisfactorily dealt with by means of a fine galvano-cautery. It has the merits of efficiency, simplicity, and economy of time. Its chief value is in the treatment of capillary and stellate navi, and even those of the cavernous

¹ A paper read before the Electro-Therapeutical Section of the Royal Society of Medicine on Nov. 19th, 1909.

Obviously, to get the best result, our aim must be to destroy as little normal tissue as possible; all we require is to set up a simple fibroplastic inflammation, which will cause a clotting of the blood in the nævoid vessels, and these in turn will become obliterated by the resulting new-formed

fibrous tissue and its subsequent contraction.

In treating a capillary nævus I first ascertain by inquiry and inspection if the growth is spreading, and if it is my first efforts are directed towards preventing this progressive increase in size. This I do by making a series of punctures, about one-eighth of an inch apart, along the nævo-cutaneous margin, so that the influence is exerted as much in the healthy skin as in the nævus itself. If the nævus is a small one, say less than three-quarters of an inch in diameter, probably nothing more will be required, and except in the large ones this is a very convenient point to stop for the first application. The growth is now safe against spreading, and it sometimes happens that the vessels feeding it are so seriously inter-fered with by what has been done that after a period of two or four weeks the growth has undergone a reduction in size as well as in depth of colour. In such a case it is obvious that there will be less to do to finish it off, and in this way we conform to the principle of destroying as little of the original tissue as possible. With the larger capillary nævi it is, of course, advisable to go over the surface as well as the margin. The punctures should be from one-eighth to a quarter of an inch apart, and, in my opinion, should go right through the whole thickness of the skin. In nearly all cases the cautery should be quickly withdrawn the moment the sense of resistance, which the skin gives, is lost. This prevents the action of the cautery extending too far.

My reasons for insisting on going right through the skin are two: in the first place it is otherwise impossible to be sure that the nævus will be affected right through its entire thickness, and secondly, because it is much less painful afterwards. You can easily understand that if you are making a lot of punctures into, but not through, the skin a number of them will be burns of the third degree—which are

intensely painful as you well know.

After a nævus has been treated in this way the immediate result is a pink scar with a somewhat pitted surface, the pits corresponding to the individual punctures. As time goes on the surface becomes paler and more uniformly smooth. In the case of children seen about 12 months afterwards the area is soft, smooth, and elastic, and as to colour scarcely to be distinguished from the surrounding skin. The pitting left by the punctures is still present, but not very noticeable. tends to become less perceptible as time goes on, but slight traces can be found years afterwards.

The high frequency spark ("fulguration").—The only class of nevi that are beneficently influenced by this method is that comprising what is generally called the "port-wine applicable where the growth only involves the superficial layers of the skin. The method of procedure is akin to that described as "falguration" and practised to some extent on the continent for malignant growths, but any ordinary highfrequency apparatus is sufficiently powerful for our purpose.

I have now treated about 20 cases by this method, some of which have had several applications. The milder ones have been cured to all intents and purposes; the more severe ones The milder ones have have been improved to an extent which is roughly inversely proportional to the severity of the original lesion. The method of making the application is familiar to everyone and so need not detain us.

From my own experience I am of the opinion that the narrower the spark-gap and the closer the metal point electrode is to the skin the more superficial is the effect produced, the more does the thermic effect predominate over the electrical effect, and the changes are produced more rapidly. I am also of the opinion that under such conditions we are more frequently troubled with keloid changes in the scar; this I attribute to the thermic effect, because I feel sure that the

disagree with me in this. It is merely a record of my own personal observations. I find, however, that any highfrequency application made with the electrode close to the skin surface, and long enough to produce at least some destruction of tissue, is very likely to be followed by keloid The minimum distance of the electrode from the changes. skin should be about three-quarters of an inch. It takes a longer time to get the desired reaction, but the effect penetrates more deeply and is less likely to be followed by keloid' With such an interval between the changes in the scar. electrode and the skin, the application is so painful that a general anæsthetic is almost always necessary, and the troubles of the anæsthetist are not made lighter by the objectionable noise, which seems an unavoidable part of the procedure. Ether must not be used on account of the risk of the vapour catching fire from the spark—this has happened once to my personal knowledge, owing to an assistant accidentally filling the usual chloroform bottle with ether.

While I consider the high-frequency spark a valuable means of treating "port-wine stains," I have almost entirely discarded it for the new method I now propose to show you. As a result of the experience I have had with the foregoing methods in this work, I look on no case as too severe to make some serious effort, especially in female children, to remove an unsightly birth mark. Practically every case can be vastly improved, while the less severe ones can be cured to all intents and purposes. With care and not attempting to do too much at one time, unsightly scarring is avoided, and deformity from cicatricial contraction kept

within the narrowest possible limits.

Refrigeration.—The methods so far described have been those employed by me almost exclusively up to midsummer of the present year. At that time Dr. Geyser of New York called on me and asked me if I would try a method employed by him for nævi and various superficial conditions that in his hands had been remarkably successful. This I put into practice forthwith, and the method is so free from the objections common to most others, and the results are so satisfactory, that I now treat more cases with it than by all the other

methods taken together.

The process is one of refrigeration and is carried out by means of the local application of solid carbon dioxide. This is obtainable in iron cylinders, containing some 20 or 30 pounds of the liquefied gas, at a pressure of over 20 atmospheres. It is obtained from the combustion of coke and finds its chief use in the mineral water industry. When the liquefied gas is allowed to escape into the atmosphere the sudden expansion causes a prodigious lowering of temperature, and it appears in the form of a white semi-solid snow. By collecting this in a suitable receptacle it can be formed at once into a comparatively hard stick or crayon, not unlike an ordinary candle in appearance. Also, it can be compressed into a mould of any desired shape or size, and subsequently cut to any form with a knife. The temperature of the frozen gas is -79° C. (110° F.).

Of course, making use of low temperatures in treatment is by no means new. On the continent cases of lupus vulgaris have been successfully treated by ethyl chloride spray. Later liquid air was tried, and I understand that two or three months ago a demonstration on the use of liquid air in dermatology was given in this room by the late Dr. Radcliffe Crocker, whose recent demise we all lament. While liquid air possesses the quality of intense cold to a degree far surpassing anything we know of, it is extremely difficult, even impossible, to use it in an efficient manner. Its liquid form is responsible for this, making it difficult to control and impossible to make use of that most important adjunct-pressure. Whatever be the agent we employ for the freezing process, the principle involved is of course the same, but that is not to say that the different agents are equally advantageous in practical use.

The point I wish to emphasise about solid carbon dioxide is that it is a solid and yet sufficiently soft that it can be moulded or cut to any convenient size or shape. Also, for the same reason, it enables us to use as much pressure as we wish and thus freeze the tissues to any desired depth within reasonable limits. A further point to be remembered is that our freezing agent maintains a constant temperature. As the tissues give up their heat to the crayon the surface of the latter becomes gaseous and escapes into the atmoscars following heat burns are more prone to keloid changes sphere. At ordinary atmospheric pressures carbon dioxide than those from other kinds of injury. Probably some will at -79° C. is a solid, at -78° C. it is a gas. The surface in contact with the part under treatment is thus being constantly renewed.

To say that the crayon is "in contact" is probably not literally correct. It is more likely that it is kept apart from the part under treatment by a thin layer of gas. For this reason, it is possible to hold a small piece loosely in the hand without discomfort. Also, if a flat disc of solid CO_2 be placed upon a level sheet of plate glass, slightly warmed, the disc can be seen to be in constant motion, and if one end of the glass be raised the disc slides down the slope with rapidity out of all proportion to the degree of inclination. It will be seen that some pressure is necessary to get any effect at all, but owing to its rigidity we can make as much pressure as may be necessary.

It is this matter of pressure that gives CO2 such a great advantage over other refrigerants. The solid gas evaporates very slowly. A crayon five inches long and one inch in diameter will last from one to two hours if left in an ordinary room. Wrapped in cotton wool it loses about half its weight in a period of four hours. such a crayon I have made over 30 applications, a piece about one and a half inches by half an inch remaining.

Dosage. - As with any other new agent, so with this-we have much to learn. There is no reason, however, why the question of dosage cannot be reduced to almost mathematical accuracy here. As we have seen, the temperature of our crayon is a constant one. Hence

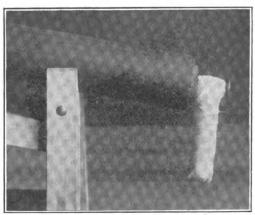

firmly pressed down, so as to drive the blood out of the part, or at least arrest the circulation. The average duration of the application will be about 40 seconds. If there is bone immediately beneath, a shorter time will do. If on a soft place such as the thigh or abdomen, it should be a little longer. A "port-wine mark" is best treated with a moderate degree of pressure, depending on the depth of the lesion. For a cavernous nævus the end of the crayon may be the same size or slightly smaller than the area of the growth. A long application with deep pressure should effectually freeze the whole mass. In any given case the time and pressure of the application will be decided by the conditions present.

The diseases curable by this agent are numerous, and, I fancy, will be of great interest to dermatologists. As I have

said, I now use it for nævi more than all the other methods I have mentioned taken together. It is very successful for moles and other blemishes; it seems to have a favourable influence on lupus erythematosus, and I have successfully treated patches of lupus vulgaris. It answers excellently for warts. In the treatment of the latter, a long application is necessary on account of the poorly conproperties of the I do not time the ducting growth. application: after trimming the crayon to the size of growth, I apply it with firm pressure until a narrow zone of healthy tissue around the base is frozen. If we stop before this the result will not be satisfactory. In the keratoses accompanying X ray

dermatitis, brief applications

Fig. 1.

the only variable factors in Showing towel secured to valve with bandages and ready for filling.

Fig. 2.

Before operation. dosage are time and pressure. There is no difficulty about the measurement of time, and a holder with a spring inside, which is adjustable, would solve the latter point. I doubt, however, if this will be necessary—but it is easy to see how the depth and intensity of the subsequent reaction could be regulated with almost absolute certainty.

I am always adverse to the use of any appliances that tend to efface the personal equation entirely, and in this case no very great experience is required to make the necessary pressure one's self. To come to practical details, take the case of an ordinary capillary nevus of moderate size, less than one inch in diameter in any direction. I trim the crayon roughly to the shape of the nævus, and I prefer

Fig. 3.

Three weeks after operation.

answer exceedingly well. The list of diseases to which this agent is applicable will probably be extended very No doubt within the next year or so dermatologists will have much to tell us on this subject.

The preparation of the solid carbon dioxide. - The first requirement is obviously a cylinder of the compressed and liquefied gas. A large cylinder is much the more satisfactory. It should be mounted on a stand at a convenient height and with the stopcock on a lower level than the opposite end, so that the liquid gas covers the inner orifice of the valve. next procedure will depend on whether we have a large or a small number of applications to make. In it to be slightly larger. It is now applied to the nevus and any case we shall require an ordinary cylindrical

ruler about an inch in diameter and a hand-towel. The latter is folded into three, lengthwise, and rolled around the ruler as tightly as possible. The ruler being withdrawn, we have a hollow porous cylinder, in one end of which we place a short, loosely fitting cork. If we have a large number of applications to make, we take an ordinary bandage and bind around the towel a few turns and apply its open end over the cylinder outlet. The bandaging is now continued in such a way as to secure the towel to the valve and make as tight a joint as is possible to do by bandaging. I find two ordinary bandages sufficient. The gas cylinder is now turned so that the valve is pointing downwards and the valve opened, allowing the space within the towel to become filled with the soft CO_2 snow, which later becomes solidified, and this is continued until it is packed firmly. (Fig. 1.)

The fixing of the towel and the management of the valve require a certain amount of practice, but it is the easiest method of getting a large firm crayon. After the valve is closed the bandages are removed, the towel unrolled, and the crayon secured with a turn or two of lint. It is now ready for use. If we require enough for one or two applications only, instead of binding the towel to the cylinder valve we hold it in place with one hand while we open the valve with The towel becomes filled with the soft snow, and we cut off the gas as soon as it begins to blow off around the We now place this snow in a metal or vulcanite tube of the desired shape and size, and pack it down hard with a suitable rammer, using a mallet if a particularly hard crayon is wanted. No matter how hard we pack it it at once frees itself, and can be pushed out quite easily. The tubes for moulding can be of any shape or size. The square one is used for doing large areas without leaving intervening spaces untreated, as would be the case if a round applicator were used.

Effects of the application.—On removing the crayon after an application the depression made by it remains; the frozen surface is pure white and hard, like a piece of china. The process of thawing occupies about the same time as the application, and the depressed tissue gradually returns to its normal place and colour and is found to be covered with moisture of condensation. Reaction sets in immediately within a few seconds the treated area is of an appreciably firmer, brawny consistency, and in two or three minutes perceptibly swollen. A wheal develops, with acute hyperæmia, within half an hour, and a vesicle frequently within an hour, but this may take longer or not develop at all in the case of a very short application. An application of 30 seconds or longer will almost certainly be followed by scarring. A very intense superficial destruction is obtained by a second application immediately after the tissues have thawed out from the first one.

With regard to the after-treatment, this is very simple. Boric acid ointment is what I use almost invariably. If a blister forms the fluid is carefully let out, and this may have to be done a second or even a third time. Within a few days a crust forms which should be allowed to come off of its own accord. The treated area is completely recovered in about a fortnight. The surface is then perfectly smooth and of a delicate pink colour, which gets paler as time goes on. The ultimate result is a pale, soft, pliable, and elastic scar which is as good as, or better than, any produced by any other caustic agent, or even radium. Like radium, and unlike the cautery or other caustic agent and electrolysis, there is no immediate destruction of tissue; the results are achieved by a reaction set up in the tissue itself, and we have a complete range of effect, from a simple mild hyperæmia which clears up in a few hours to a complete necrosis. Unlike radium. it is cheap, and instead of waiting days or weeks for a reaction we get this within a few hours. I predict that it will displace radium for many of the purposes for which the latter is now used.

I show some results obtained. In a photograph they do not differ greatly from those treated by other methods, and no good purpose would be served by showing a number. (Figs. 2 and 3.) These are typical of the results. In the majority of cases a single application lasting from 30 to 60 seconds is all that is necessary. If the cure is incomplete a second one can be made as easily as the first.

The application is practically painless, and no anæsthetic is ever necessary. I have had children who never moved or cried during the application. The majority do make a noise, but this is more because they are held still than of the pain. In the remaining three cases the children

It is a curious fact that many adults voluntarily say, "It is beginning to hurt now," at about the twenty-fifth second. The "thawing out" is more painful and uncomfortable than the freezing. With regard to time, two or three cases can be finished off while one is being anæsthetised for electrolysis or cautery. I have treated 30 cases within an hour and a half.

I have not yet seen any keloid in the resulting scars, nor have I had an opportunity of examining the changes that take place in the frozen tissue. It is quite possible that at this very low temperature changes other than those following ordinary frost-bite would be found. Ordinary frost-bite lasting no more than 60 seconds does not produce anything like the same degree of reaction that we get with solid carbon dioxide. With the fixation and rigidity which occur just below freezing point, followed by the expansion of the frozen liquid part of the tissues, which must take place with this extreme lowering of temperature, it is conceivable that the cells are mechanically injured, the reticulum broken down, and the cell-wall burst, just as a bottle full of water is fractured after being left outside on a frosty night. This would at least account for the immediate and profound reaction that occurs after application. This, however, is conjecture, and I shall be glad to have the views of others regarding this question.

To say that solid carbon dioxide is merely a caustic, as some have asserted, is not quite correct. All caustics, strictly so-called, destroy tissue immediately—e.g., the actual cautery, and various chemical substances—but CO does not do so. After the part has thawed out, the whole of the treated area is still living, as evidenced by the intense reaction which sets in. Local death may occur later, owing to inflammatory stasis; but this is the result of a vital reaction, and not an immediate result of the application of the irritating substance.

In conclusion, I wish to apologise for such a lengthy paper, but I am sure it will be agreed as to the value and importance of this interesting and fascinating substance as a therapeutic agent. Personally, I look upon solid carbon dioxide as the most important addition to the dist of physical agents employed in therapeutics since that of radium, and, as I have already stated, I predict that it will be found to compete successfully with radium in the treatment of many superficial lesions.

THE INFLUENZA BACILLUS THE CAUSE OF AN EPIDEMIC OF BRONCHO-PNEUMONIA.

BY T. STACEY WILSON, M.D. EDIN., M.R.C.P. LOND., PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM;

AND

JAMES MILLER, M.D. EDIN., M.R.C.P. EDIN., VISITING PATHOLOGIST TO THE GENERAL HOSPITAL AND LECTURER ON BACTERIOLOGY TO THE UNIVERSITY, BIRMINGHAM.

THE cases which came under the personal observation of one of us were five in number and embraced all the children in one family, but there were also two other children in an adjoining house who suffered from pneumonia at the same time. The history of the five cases is as follows:—

In October, 1908, one of us was asked by Mr. R. Clayton Morris to see the children of a certain Mrs. A who were suffering from pneumonia. All five children, their ages varying from 12 months to 9 years, were in bed in one room, three of them dangerously ill with pneumonia and the other two less seriously. The previous history was that all had been strong and well with the exception of the oldest, a girl aged 9 years, who was said to have had tuberculous peritonitis some years ago and had made a good recovery from it. The history of the onset of the illness was as follows. The first of the children to fall ill was a boy aged 7 years, who sickened on Oct. 12th, and was quickly followed during the next two days by the other four children. They became feverish and ill without any definite rigor, although most of them vomited at the commencement of their illness, and two of them—namely, the first two—commenced with pains in the limbs and sore throat and were supposed to have influenza. In the remaining three cases the children

simply became feverish and rapidly developed lung symptoms. None of them had herpes labialis. One of us saw the children on the third day after the onset of symptoms (Oct. 14th) and the condition of matters was tragic in the extreme. All of them had bronchopneumonia involving both lungs, and three of them had temperatures of 102° F. or over, a pulse-rate of over 140, and respirations over 70 per minute. The two worst, the boy aged 7 years and a girl aged 2, were unconscious, and the boy evidently had not long to live. The boy was too ill to be moved, but the two younger girls were admitted to hospital, leaving the baby and the oldest girl, who was not very ill, to be nursed at home, as the mother's resources were somewhat limited. The pneumonia was of bronchopneumonic rather than of lobar type, the dulness and tubular breathing not being so extreme and extensive as in pneumococcic pneumonia. The boy never rallied at all and died on Oct. 15th, the fourth day of his illness. The girl aged 2 years died on the fifth day of her illness, gradually sinking in spite of all that could be done, and the other three children recovered, the two older girls somewhat rapidly and the baby after three weeks' illness.

An endeavour was made to ascertain the nature of the micro-organism causing the condition, both by taking cultivations from the organs of the boy who died on Oct. 15th and by cultivations from fluid obtained by exploratory puncture of the consolidated lung from the children in hospital; but no organism was isolated until the organs from the child who died in hospital were carefully investigated. The ears of the children were carefully examined, but suppurative otitis media was not the cause of the severity of the symptoms. In the case of the girl who died in hospital there was some congestion of the left membrana tympani two days prior to her death, but no suppuration, although at the necropsy pus was found. Clinically the remarkable feature of the cases was the suddenness with which all five children were attacked and the severity of the pneumonia in each case.

Necropsy. - A post-mortem examination was performed by one of us on the body of the girl, aged 2 years, who died in hospital, on Oct. 19th. The body was that of a well-developed and well-nourished child. Rigidity was present but not marked. There was some lividity of the lips. There was nothing of note in the heart. Both lungs showed a recent acute fibrinous pleurisy; both showed irregularly distributed purple areas scattered over the surface with intervening paler areas, the typical appearances in lobular pneumonia. On palpation numerous solid nodules could be felt. On section the lungs appeared congested with more darkly coloured solid nodules scattered through their substance. The bronchi contained some secretion and their mucous membrane was congested. The bronchi contained some The bronchial glands were enlarged and congested. The peritoneum showed chronic inflammation, evidenced by thickening of the capsule of the liver and spleen. liver and the kidneys showed fairly well-marked cloudy liver and the kidneys snowed rain, non swelling, and the spleen was slightly enlarged, and, on Malnighian bodies. The vessels of the brain were congested and there was some excess of cerebro-spinal fluid. Both middle ears contained pus.

The surface of one of the lungs was seared, an incision was made with a sterile knife, and portions of the fluid exuding from the lung substance were inoculated into broth and blood agar. No growth was observed on the first day, but after 48 hours minute, discrete, translucent colonies were visible on the blood agar. The broth also showed some turbidity. On examination the organism was found to be a very minute bacillus, although at first it had the appearance of a coccus. The organisms occurred singly or in pairs, endto-end. They stained fairly readily with ordinary stains, but dilute fuchsin gave the best results. The Gram reaction was negative. The organism did not grow well on broth or agar, but on blood agar the growth was fairly profuse, the colonies being barely visible to the naked eye after 48 hours and did not become subsequently much larger. They were most numerous at the margins of the blood streaks. It was found that subcultivation every week or ten days was sufficient to keep the cultures alive. In this way the organism was kept growing for five or six months. After some months, however, microscopic examination of the growth showed very remarkable appearances. The bacilli were on an average larger, some were thin, and others thick and club-shaped;

filamentous forms were not infrequently observed. Soon after the organism was isolated a strong emulsion of it was made in normal saline and injected into the ear vein of a rabbit. The animal did not develop any symptoms at all. At first we had little difficulty in concluding that the germ was the influenza bacillus. Later on, when the involution forms appeared, we had som doubt as to its identity, but when we found that such forms have been frequently described in connexion with old cultures of the organism, notably by Grassberger, the fact merely confirmed us in our original conclusion. We are indebted to Dr. C. J. Lewis for assisting us to classify the germ.

Microscopic sections of the lung showed the usual appearances of a capillary bronchitis and broncho-pneumonia, and sections stained with dilute fuchsin showed minute bacilli in small numbers in alveoli and bronchi similar to those cultivated.

Pathologically the chief points of interest in the cases are the epidemic nature of the disease and the occurrence of the influenza bacillus as the only organism present in the lung in one of the cases. From the occurrence of the cases at one and the same time, and from the fact that cultures upon ordinary media failed to show any growth in the other fatal case, one may fairly conclude that the causal germ in all the other cases was the influenza bacillus. The occurrence of this germ in broncho-pneumonia has long been recognised, and the fact that it is not infrequently the only organism present in the lungs is emphasised by Fraenkel.² The main point of interest in the present instance is therefore the occurrence of the influenza bacillus as a cause of a number of cases of broncho-pneumonia arising so obviously in connexion with one another as to warrant the term epidemic.

EIGHT CASES OF EXTERNAL ANTHRAX.

By RANDAL HERLEY, B.A. R.U.I., L.R.C.S., L.R.C.P. EDIN.,

LATE HOUSE SURGEON, GENERAL INFIRMARY, DEWSBURY.

CASE 1.—A man, aged 23 years, a willower, was admitted to hospital at 5.45 P.M. on April 12th, 1906. On April 9th the patient noticed a sore on the left upper eyelid. On the 10th the eyelid was swollen and he was not able to open the eye; there was no pain. On the 11th the left side of the face began to swell, and on the 12th he saw his medical attendant who advised him to go to the infirmary. admission the temperature was 101.2° F. and the pulse was The left upper eyelid was swollen and covered with vesicles; there was a red inflammatory zone just below the eyebrow. The left side of the face was swollen and brawny as far as the angle of the jaw; there were no enlarged glands, no soreness of the throat, and no history of vomiting or shivering. Owing to the position of the pustule it was decided not to excise it. At 9 P.M. 40 cubic centimetres of Sclavo's serum were injected subcutaneously. On April 13th the temperature was 101.43, the pulse was 104, and the respirations were 22. The left side of the neck was swollen. 40 cubic centimetres of serum were injected subcutaneously, and also, close to the pustule, 10 minims of carbolic acid solution (5 per cent.). The evening temperature was 103.4° and the pulse was 106; the patient vomited four times during the day. On the 14th the temperature was 103.40 and the pulse was 110. I injected 30 cubic centimetres of serum and also 10 minims of carbolic acid solution. There was no improvement in the condition of the patient. On the 15th the temperature was 102°, the pulse was 104, and the respirations were 20. The right side of the face and neck was swollen and the left cheek was covered with vesicles; 10 minims of carbolic acid solution were injected. On the 16th, at 1.30 A.M., the right eye was closed and the cedema now involved the chest as far as the nipples. I made four incisions, two on the forehead and two on the left side of the face. At 10 A.M. the temperature was 100° and the pulse was 108; the œdema of the face was less; 40 cubic centimetres of serum were injected. On the 17th the condition of the patient was much improved; there was eversion of the left upper eyelid owing to cedema of the conjunctiva.

Grassberger: Centralblatt f
 ür Bakteriologie, Band xxiii., 1898, S. 353.
 Fraenkel: Spezielle Pathologie und Therapie der Lungenkrankheiten.

The temperature was 100° and the pulse was 108, on the 18th falling to 99° and 100 respectively. There was also on the 18th considerable diminution in the cedema of the face, neck, and chest. I injected 20 cubic centimetres of serum; the left cornea was clear. On the 19th the local and general condition of the patient was much improved. I incised the swollen conjunctiva; the temperature was 100.4° and the pulse was 100. On the 20th there was a rash all over the body; he complained of pains in the back, thighs, and right elbow. I prescribed aspirin, 10 grains, thrice daily. The temperature was 99° and the pulse was 112; 20 cubic centimetres of serum were injected. On the 21st the temperature was 101.4° and the pulse was 110; there was a large slough on the left upper eyelid. The cedema of the face, neck, and chest was considerably diminished. On the 22nd the temperature was 100.80; the pains were not so severe and the rash was disappearing. On the 23rd the temperature was 99° and the pulse was 80. The patient's condition was much improved and he was evidently out of danger. On May 2nd he was photographed; the slough on the eyelid and the swollen conjunctiva are well shown (Fig. 1). On May 14th the slough was removed; and on June 12th, the ulcer having healed, I

and on the 31st he was shaking wool which had passed through the willow-machine. On the evening of the 31st he felt a "sore place" on the right side of the neck; there was no swelling. On Nov. 1st he went to work at 6.30 A.M.; the right side of the neck was swollen; he had no pain. During the day the right side of the face began to swell, and about 10 P.M. he saw his medical attendant, who sent him to the infirmary. On admission the temperature was 100.4° F., and the pulse was 108; the tongue was clean. On the right side of the neck, about 2 inches below the lobule of the ear, there was a well-developed anthrax pustule. There was cedema of the right side of the face and neck. No enlarged glands could be felt. There was no history of vomiting, sore-throat, or shivering. On Nov. 2nd, at 12.30 A.M., under chloroform, I excised the pustule and injected 40 cubic centimetres of Sclavo's serum. The boy slept well during the night. At 10 A.M. the temperature was 101° and the pulse was 96. The face, neck, and upper part of the chest were very edematous. The patient was drowy. At 6 P.M. the temperature was 102°, and the pulse was 112. He vomited once. At 11 P.M. I injected 40 cubic centimetres of serum. On the 3rd the temperature was 100.6° and the pulse was 110. The boy vomited twice. incised the scar and removed the thickened conjunctiva. The face, neck, and chest were very much swollen; the

FIG. 1.

Case 1.—Slough on the eyelid and swollen conjunctiva before operation.

The lids were brought together with Pagenstecher's thread, right side of the neck and face was hard and brawny and The patient was discharged on July 14th. Fig. 2 (reproduced from a photograph taken in September, 1906) shows the result of the operation.

CASE 2.—A married woman, aged 32 years, a weaver, was admitted at 10.45 A.M. on June 1st, 1906. On May 27th she noticed a "heat lump" over the left eyebrow, on the 29th there was some swelling around the sore, and on the 30th she complained of pain below the left ear, and was unable to open the eye. She consulted her medical attendant on the 31st and was advised to go to the infirmary. On admission the temperature was 100° F. and the pulse was 110. About half an inch above the left eyebrow there was a typical malignant pustule; the forehead, eyelids (left) and left side of the face and neck were cedematous. Two enlarged glands were felt below the left ear. She did not complain of sore-throat; there was no history of vomiting or shivering. Under local anæsthesia (cocaine and adrenalin) I excised the pustule and injected 40 cubic centimetres of Sclavo's serum. The cedema disappeared rapidly and the patient felt quite well in a few days. On June 10th, by undercutting the skin all round the ulcer, I was able to bring the edges almost together. This patient left the hospital on June 13th. I saw her on March 20th, 1909, and the scar was scarcely visible.

CASE 3.—A youth, aged 18 years, a wool-shaker, was admitted at 11.30 P.M. on Nov. 1st, 1906. On Oct. 29th and Case 4.—A girl, aged 14 years, a hanker, came to the 30th this boy was "packing sheets of wool" for the willower, infirmary on March 4th, 1907. On Feb. 27th she noticed "a

Case 1 .- Result after operation.

covered with vesicles. The patient was very restless and had difficulty in swallowing. At 6 P.M. the temperature was 101.20, and the pulse was small and rapid. At midnight I made four incisions and injected 20 cubic centimetres of serum. On the 4th the boy's condition was very bad; the temperature was 97.6°. I was unable to count the pulse. At 7.30 P.M. the temperature was 99 · 8°, the pulse was 130, he had difficulty in swallowing, and the breathing was stertorous; he vomited several times. 20 cubic centimetres of serum were injected. On Nov. 5th the temperature was 100 · 6° and the pulse was 130; there was very little change in the ædema. There was a thick cloud of albumin in the urine. At 6 P.M. the temperature was 101 · 20 and the pulse was 136; the boy was restless and had great difficulty in swallowing; 40 cubic centimetres of serum were injected. On the 6th at 4 A.M. the boy was very restless; the pulse was quick and irregular. I changed the dressing and injected liquor strychninæ (5 minims). At 6 A.M. the nurse came to my room and said that the boy was much worse. When I reached the ward he was dead. No post-mortem examination was made, the coroner being satisfied with the bacteriological report from the Public Health Laboratory, Wakefield. Figs. 3 and 4 are reproduced from photographs taken, one six months before the boy's fatal illness and the other on Nov. 4th at 2 P.M.

sore" on the front of the right forearm. She saw a herbalist on March 1st and was told to apply poultices. On admission there was a well-developed malignant pustule on the front of the right forearm about four inches above the wrist and the forearm was swollen as far as the elbow. The temperature was 100° F. and the pulse was 84. Under an anæsthetic the pustule was excised and 40 cubic centimetres of Sclavo's serum were injected subcutaneously. The local and general condition of the girl improved rapidly, and she was made an out-patient on March 23rd. She was discharged on April 27th. This girl came to the hospital on March 21st, 1909, and on the forearm there was a thin depressed scar about the size of a florin.

CASE 5.—A schoolboy, aged 13 years, was admitted at 11 A.M. on August 23rd, 1908. The following history was obtained. After school hours the boy usually "took the to one of the men employed by a hide and skin merchant, and he generally spent the afternoon helping the men in the warehouse. On August 20th he noticed a "heat spot" on the left side of the face. On the 22nd his face began to swell and he felt cold. On admission the tongue was clean; the temperature was 100.6° F., the pulse was 108, and the respirations were 24. The pustule was on the swollen, and on the front of the forearm, about 3 inches left cheek close to the angle of the jaw; the left side above the wrist, there was a typical anthrax pustule. There of the face and the upper part of the neck were swollen. were several bulke on the forearm; no enlarged glands were

three-quarters of an inch in length and half an inch wide, surrounded by an extensive ring of vesicles. The right side of the face and neck was swollen and the right eve was closed. This was the largest malignant pustule that I have seen. At 3 P.M. 40 cubic centimetres of serum were injected subcutaneously and a boric acid fomentation was applied. The pustule was not excised. There was no reaction after the serum. The local and general condition of the patient improved rapidly and he felt quite well in a few days. He was made an out-patient on Sept. 12th and was discharged on Oct. 3rd. In reply to a post-card he came to the infirmary on March 18th, 1909. The scar, thin and depressed, was scarcely visible.

CASE 7.—A man, aged 44 years, a farmer and butcher, was admitted at 3 P.M. on Oct. 4th, 1908. About ten days before admission he received a scratch on the front of the left forearm. On Sept. 28th one of his cows died suddenly, and he skinned and cut up the carcass the same day. The meat was sold to the "neighbours" and the hide to a fellmonger. On admission the tongue was furred, the temperature was 103.3° F., the pulse was 92, and the respirations were 24. The whole of the left upper extremity was swollen, and on the front of the forearm, about 3 inches

Fig. 3.

Case 3.—Reproduction of photograph taken six months before fatal illness. At 8 P.M., under an anæsthetic, 80 cubic centimetres felt. He complained of headache and "cold shivers": of Sclavo's serum were injected under the skin of the abdomen. The pustule was not excised. At 10 P.M. the temperature was 101.6°. On the 24th the temperature was 99.40 and the pulse was 88; the ædema was much less and the boy's general condition had improved. On the 25th the pulse was 80, the temperature was 97.8°, and the respirations were 18. He complained of slight pains in the back and limbs and there was a rash on the chest and abdomen. The cedema of the face and neck was considerably diminished. The boy was made an out-patient on Sept. 2nd, and he was discharged on Oct. 16th. In reply to a postcard he came to the infirmary on March 18th, 1909; at the angle of the jaw

Case 6.—A man, aged 55 years, was admitted at 1 P.M. on August 29th, 1908. This patient had not worked for several months, but his wife was a "condenser-minder" in a wool mill. The following history was obtained. On August 25th the patient washed a blouse usually worn by On his wife to protect her clothing whilst at work. On the 26th he noticed a pimple on the right side of the face close to the eye, and on the following day his face was swollen. On admission the temperature was 98.6° F. and the pulse was

there was a thick scar about a quarter of an inch long.

Case 7.—Reproduction of photograph taken Nov. 4th, at 2 P.M., shortly before death.

there was no history of vomiting. At 6 P.M. 40 cubic centimetres of Sclavo's serum were injected and the arm was placed in an izal bath. The pustule was not excised. On the 5th the temperature was 103.4°, the pulse was 92, and the respirations were 24. The arm was much worse; there were numerous bullæ on the forearm, and a few on the upper arm. There was no vomiting; the urine was free from albumin and sugar. At 12.30 P.M. 40 cubic centimetres were injected (10 cubic centimetres intravenously). At 5 P.M. I made three incisions along the front of the forearm and one in the back of the hand. The cut tissues were of a greyish colour and gelatinous. The temperature was 104° and the pulse 110 (10 P.M.). On the 6th the temperature was 100.40 and the pulse was 104. The upper arm was incised and 30 cubic centimetres of serum were injected. He was rather better. On the 7th the temperature was 99.8° and the pulse was 88; the patient was better in every way. On the 8th there were signs of delirium tremens; the pulse was 80 and the temperature was 98°. I prescribed bromidia, one drachm every three hours. At 11 PM. a quarter of a grain of morphia was injected. On the 9th at 1.30 A.M. the patient got up and pulled the 82. Over the right zygoma there was a necrotic patch about bandages and dressing off. He became very violent and after a struggle I injected half a grain of morphia into the left leg. He slept for several hours. On the 10th the temperature was 98° and the pulse was 70. The addena of the arm was considerably diminished, but near the pustule a large area of skin showed signs of sloughing. The general condition of the patient was excellent. On removal of the gangrenous patch it was seen that some of the flexor tendons were going to slough. He would not consent to have the ulcer skingrafted and he was made an out-patient on Oct. 31st. There is an ugly puckered scar just above the wrist and considerable impairment in the mobility of the fingers and hand.

As stated before, the carcass was sold to the neighbours at reduced prices, and probably over 100 persons partook of it. The patient and a butcher who assisted in dressing the carcass contracted external anthrax on the forearm, and one woman who handled the raw meat developed a malignant pustule on her face, but no case of intestinal anthrax was recorded. A second cow contracted the disease and was cremated in the orthodox fashion. The most probable source of infection was the dust from a willow machine in a mill being carried by the wind to the field in which the cows were pasturing. The butcher and the woman were treated

by Dr. Leslie Milne, Mirfield, and both recovered.

CASE 8.—A man, aged 52 years, a rag-grinder, was admitted at 9 P.M. on March 13th, 1909. The following history was obtained. He was working on a "blend of merino and wool," and on March 9th he noticed a pimple on the front of the right forearm, a few inches above the wrist. On the 11th the sore was larger and the forearm was swollen; he went to work as usual. He vomited once on the 12th and noticed a "red ring" around the sore; there was some increase in the swelling. On admission the temperature was 100.6° F., and the pulse was 116; about 3 inches above the wrist there was a well developed anthrax pustule; the forearm was swollen as far as the elbow; no enlarged glands were felt. He was perspiring freely. About 9.20 P.M. a swab was taken for bacteriological examination. On the 14th the temperature was 100.8°, and the pulse was 80. There was no change in the local condition. At 4 P.M. Sclavo's serum-40 cubic centimetres-was injected subcutaneously and a fomentation was applied to the forearm. The temperature at 5 P.M. was 101.80 and at 7.30 P.M. a second swab was taken for examination. On the 15th the temperature was 99.20 and the pulse was 82. The general condition of the patient was good; there was no change in the local condition. At 1 P.M. a third swab was taken. On the 16th the temperature and pulse were normal. The swelling of the forearm was much less. At 12.20 P.M. a fourth swab was taken. The patient left the hospital on the 23rd and was made an out-patient. On March 18th I received the following report from the Public Health Laboratory, Wakefield: "Re Specimens VI., Nos. 31, 32, 35, and 36. The culture obtained from Specimen VI., No. 31, received from you on Sunday, the 14th March, was inoculated into a guinea-pig and caused death 24 hours later, anthrax bacilli being recovered from the blood. I failed to find any anthrax bacilli in the specimens received 15th March (32), 15th March (35), 17th March (36)."

Remarks.—Before Sclavo published the results of his trials of serum-therapy, the treatment usually recommended in cases of external anthrax was excision of the necrotic patch and of the infiltrated tissues around, followed by the application of pure carbolic acid or the actual cautery. Since 1899 several cases have been treated successfully in Italy with serum alone, and during the last few years this method of treatment has been carried out in England, combined with excision or alone. Since 1905 nine cases of cutaneous anthrax were treated in the General Infirmary, Dewsbury: in four cases the pustule was excised and serum was injected, one case was treated with serum and three injections of carbolic acid solution, and four cases with serum alone. During the same period three cases were treated by private practitioners in Dewsbury: in two cases the pustule was excised and serum was injected; one case was treated with serum alone. Of the 12 cases one was fatal—8.3 per cent.

Case 1 was a virulent type of the disease; the patient received 190 cubic centimetres of serum in eight days, and his recovery must be attributed to it. In Case 3 the boy walked into the ward and undressed without assistance. After excision of the pustule cedema increased so rapidly that I regret not having treated the case with serum alone. Dr. Legge¹ states that "examination of the notes on 64 cases treated in St. Bartholomew's Hospital and Guy's Hospital shows that in 10 ordema increased after excision, and in a small number of the deaths in London hospitals generalisation of the disease followed so quickly after excision as to raise suspicion that they were connected." Case 7 was a very malignant type of the disease and the patient owes his recovery to Sclavo's serum, of which 110 cubic centimetres were administered in two days.

I am indebted to the visiting staff of the infirmary for permission to publish these cases.

Dewsbury.

LOCAL SEPSIS AS A FACTOR IN RHEU-MATISM AND GOUT.

BY C. WYNN WIRGMAN, M.D., B.S. LOND., F.R.C.S. ENG.,

ASSISTANT DENTAL SURGEON, MIDDLESEX HOSPITAL; ASSISTANT DENTAL SURGEON, NATIONAL DENTAL HOSPITAL.

THE microbic hypothesis of the origin of gout, rheumatism, and rheumatoid arthritis appears to be generally accepted in the recent literature of the subject. The distinction between the various forms of these diseases tends to disappear as it becomes more recognised that the many intermediate types shade off so gradually into each other that no sharp dividing line can be drawn between them. Radiography lends its support to this view. The plates of the various types are hardly to be differentiated without knowing the previous history. Elsewhere our views as to the probable foci of infection have been explained, but a brief recapitulation may be useful. Our attention was called to the possibilities of an original septic cause for the above maladies some time ago, and since then we have made it a routine practice to examine every such case thoroughly for any possible local sepsis. In every case such a condition has been found. In the majority of adult cases pyorrhœa alveolaris is the most common initial lesion, tonsillar sepsis to a lesser degree, but still not infrequent. Nasal disease has also been found, but is very rare in comparison with the previous two in adults; but in children adenoids and septic tonsils are the prevailing septic foci. Not one single case of rheumatism or gout has been found without some accompanying local sepsis. Of course, this has long been realised in an inverted way, for "rheumatic tonsillitis" and "gouty gums" are among the most ancient of medical terms.

As stated above, there are various situations where the sepsis may originate. Most of them are well recognised and no description is needed either of their appearance or potentialities -most, but curiously enough not the one to which we believe the majority of cases occurring in adult life can be traced, i.e., pyorrhœa alveolaris. This paper will therefore deal principally with this form of septic infection. We wish it to be clearly understood, however, that it is not supposed to be either the sole source of infection in every case of these affections nor to give rise only to these particular diseases. On the contrary, it is allowed nowadays to be of the utmost importance in the anæmias and in many This, however, is well derangements of the digestive tract. recognised, while we venture to think that its rôle in the

diseases here discussed has been overlooked.

The types and signs, therefore, of this particular infection may be briefly described. The term "pyorrhœa" has been used for the sake of brevity and convenience to indicate any form of oral sepsis. Strictly speaking, it should connote the presence of pus. Actual pus, however, is by no means invariably present. Pyorrhœa, then, used in a general sense, in this paper may indicate any of the following types. 1. The superficial inflammation around the teeth in ill-kept mouths, which, once restored to a healthy condition, can be kept in order by the patient's own efforts. 2. Pockets

¹ The Milroy Lectures on Industrial Anthrax, March 7th, 9th, and 14th, 1905, by T. M. Legge, M.D. Oxon., D.P.H. Cantab. See THE LANCET, March 25th, 1905, p. 765.

2 Clinical Journal, February, 1909.

between the gum and tooth and osteitis of the bony sockets found on examination in apparently well-kept mouths. A characteristic odour can nearly always be detected in these cases. The patients themselves frequently complain of some alteration in, or loss of, taste, and of tenderness or aching of varying intensity due to exposure of dentine. 3. The genuine pyorrhæa, acute or chronic, where true pus can be squeezed from around the necks of infected teeth. 4. Dry osteitis, with absorption and recession of gums, which very frequently merges into 3. 5. Any combination of the

The formation of pockets of pus, leading to recession of gums, is invariably secondary to pyorrhea and is due to the absorption of the supporting bone by chronic infective osteitis. Spongy and bleeding gums, and pus which can be expressed from the sockets, are all typical symptoms of this condition. Frequently the patient does not complain of toothache and many of the cases have quite good teeth. Caries is very often entirely absent. The exciting cause of pyorrhea is not clear; possibly it is sometimes due to the tooth-brush as generally used. This is never surgically clean, and the stiff bristles must often lead to wounds of the gum around the tooth. Few people realise that no brush will clean the interstices of the teeth where food lodges and decomposes. Floss silk is the only means of removing this debris.

If we grant, then, that chronic sepsis may be a determining factor in the onset of a rheumatic or gouty attack, there are two questions which arise: 1. Is a chronic sepsis always present in these cases? 2. May a chronic sepsis exist without rheumatism or gout? To the first the answer, in our experience, so far is Yes. To the second, Yes, also. Until the bacteriology of the mouth is better known we cannot tell whether this may be due to a variation in the organisms or to soil resistance. have an analogy in the case of diphtheria, where the Klebs-·Löffler bacilli may exist in the air passages without giving rise to any symptoms. The next question is whether the attack consequent upon oral disease is due to absorption viâ the intestines or to local extension $vi\hat{a}$ the gum and bone. It appears to be possible in both ways. A very frequent result of the first cleaning of a septic mouth is an attack of rheumatism. It is not an invariable result, but seems to depend a good deal upon the amount of injury to the soft tissues in the cleaning manipulations. tend to disappear after the first few treatments. observers have noticed the correlation between diseases and pyorrhœa but have not found it in every This may be due to the fact that it is quite unusual to find members of the dental profession who recognise the condition at all. Therefore it may be missed in a case where, to those who know how to look for it, there is abundant evidence of its presence. Again, it may be that the septic focus does not exist in the gums but in the nasal cavities or the naso-pharynx. In women, as Dr. W. P. Herringham has recently reminded us, the sepsis may be found in a chronic uterine or vaginal discharge. His paper is most suggestive, and this possibility should never be overlooked in a female patient.

In the treatment of these diseases it is obvious that our attention should first be directed to the septic trouble. Once this has been discovered, if early enough, or before general symptoms have developed, we may hope to benefit the case immensely. If, on the other hand, it is only noticed after years of illness, though it may, and should, be removed, yet we cannot hope as a general rule to do more than arrest the progress of the disease and alleviate pain. For, consider, if we grant that an inflamed joint is due to the fact of an organism settling there, there are two possibilities in the future history. One is that the germ, after setting up inflammation, dies, and no further trouble occurs unless a fresh invasion takes place. The other possibility is that the acute inflammation caused at the first onset dies down because of the attenuation of the virus or from other causes, but the microbe, having effected a lodgment, bides its time and multiplies locally, causing chronic irritation. In the first case we may evidently do good by checking the chance of fresh invasions; in the second only general treatment or surgical interference can be of any avail. Vaccines, except in cases where an unmixed infection is present, do not appear to be of much value. The answer, therefore, to those who hastily

deny the possibility of this hypothesis and line of treatment is that there are the above modes in which the diseases may differ, and, once the second has taken place, cure, though possible, is only remotely probable, while in the first it is both possible and probable.

One great, possibly the greatest, difficulty is the length of treatment the gums require. Patients cannot realise that it is often practically impossible to cure the condition without removing teeth in order to isolate and render accessible for cleansing purposes those remaining. A so-called "cure" takes place by the dropping out of the teeth; but frequently the bone remains in a more or less diseased and inflamed state even when the mouth is edentulous. There can be no question that it is important, if only for the sake of the digestion and general health, to improve this local condition as far as possible, even though it may be too late to cure the gouty or rheumatic symptoms.

Let us now examine the various types of the rheumatic and gouty groups with the septic conditions found (see table).

These cases are not "selected" in any sense of the word. The trouble in some is of recent origin, in others of old standing. Nearly all, after thorough local treatment, have found themselves better in health than they have been for years. The treatment of some of these cases throughout has been entirely confined to the local cause of infection without general treatment. In others, general treatment has been concurrent with the local treatment. The local treatment adopted has been very careful cleansing of all teeth, gums, and pockets, avoiding as much as possible injury to the soft tissues. In cases where efficient drainage of pockets could not be obtained, extraction has been done, as it is much better to leave a tooth isolated, especially if it has a good opposing tooth for mastication, than to have a number of teeth on either side with foul septic pockets. In the very septic cases, when there was no hope of the teeth becoming firm under treatment, extensive extraction has been carried out.

In all cases of extraction, before operating, all the teeth and pockets have been, as far as possible, very carefully cleansed. This is a most important point, as very serious infection of bone and general septicæmia may follow extraction of septic teeth. In every case citric acid (3 drachms to the pint) dissolved in a warm solution of carbolic acid (1 in 40) is used as an antiseptic and astringent for the cleansing of the pockets. All the tartar is removed and the teeth and gums are swabbed round with the warm solution. Wisps of cotton wool soaked in the solution are carefully passed into any septic cavity by means of a sterile platinum probe. The process is very tedious, as it takes about an hour to clean a mouth thoroughly. About six visits are usually required for obtaining a good result. General and local improvement is generally marked after the first two or three visits. It is of interest to note that on the following day, subsequent to the local treatment, the symptoms are frequently worse, due to slight unavoidable injuries to the local tissue and consequent increase of local infection.

Having cleansed the mouth satisfactorily, and so removed the septic infection, it must be borne in mind that, except in cases of complete extraction or isolation of teeth, there must always remain pockets and sites for the accumulation of septic matter and subsequent re-infection. It is futile trying to make oneself believe that the pockets are cured, particularly in the great spaces between molars, consequently the patient must learn to clean the gums and the spaces between the teeth besides using the toothbrush; in other words, must begin for the first time to try to obtain a clean and healthy mouth. If in childhood it could be taught that it is absolutely essential, besides cleaning the enamel of the teeth, to clean the gums and spaces between teeth at night, the prevalence of septic and unhealthy mouths among cleanly and educated people would be avoided.

It is not suggested that local treatment is the only desideratum in every case of rheumatism or gout. In acute gout colchicum, and in rheumatism salicylates, must also be exhibited, while for the local conditions much may be done by means of radiant heat and electricity. These, however, are all directed to the relief of symptoms and do not strike at the root of the matter. Let us now go into a more detailed examination of a few selected cases.

Some Cases, with Details of Treatment.

CASE 1.—The patient, a man, aged 45 years, was seen on June 24th, 1909. He complained of general debility, rheumatism, and excessive tenderness of the feet whilst and after walking; in fact, he was unable to walk more than 400 yards without a stick. As regards local sepsis, there was pyorrhea, with large pockets between the molars. Five or six of the back teeth had been lost. His mouth was treated, as explained above, six times in three weeks, an hour at a time being given to the process. The condition was then distinctly better, but he still complained of pain on walking. On July 19th the lower right wisdom tooth was removed. Very large pockets existed between

it and the 12-year old molar. Marked improvement followed, and in a week he was able to walk a couple of miles without any pain. Another tooth had to be removed, but on Oct. 12th, in all a period of about three and a half months, he reported that he was practically well, felt better than for years past, and could walk five or six miles with ease. No other treatment of any kind except cleansing of the mouth was employed.

CASE 2.—The patient, a man, aged 35 years, complained of lumbago, rheumatism in the arms and legs, and general debility. He also showed signs of neurasthenia with vertigo and dizziness. Eustachian catarrh was present. As to local sepsis, there was pyorrhœa; the lower left molars were loose and badly infected. After careful cleaning with carbolic they

Gout.

No. of case.	Age in years.	and the	Septic focus.			
1	50	Acute attack in right tarso-metatarsal joint, great toe. Has had many attacks. This one followed three days after the commencement of a carbuncle on the neck.	Well-marked pyorrhæa.			
2	33	Has had three attacks in past two years : two in right great toe, one in extensor brevis of right foot.	Pyorrhæa.			
3	71	Repeated attacks, especially in great toe joints, for last 20 years. Has also had eczema.	,,			
4	48	Repeated attacks. Last in right great toe.	Supra-tonsillar recess full of pus. Tonsils also septic.			
5 .	29	Several attacks. Very susceptible to lead-poisoning,	Bad pyorrhæa			
6	56	Repeated attacks. Also rheumatic.	Pyorrhoa. Some artificial teeth Plates very foul.			
		Acute Rheumatism.				
7	20	Rheumatic fever 9 years ago.	Bad pyorrhœa.			
8	49	Rheumatic fever 8 months ago. Double mitral disease.	Very bad pyorrhœa.			
9	65	Rheumatic fever 3 times in 25 years. Another attack recently.				
10	5	Repeated attacks of subscute rheumatism, temperature running up to 105:5° F., pains in knees and ellows. Systolic bruit at apex.	Hypertrophied tonsils and adenoid			
11	3 0	Acute rheumatism.	Pyorrheea.			
		Rheumatoid Arthritis.				
12	62	Synovitis in right knee some years ago. Now has fluid in left knee; some crackling on movement.	Bad pyorrhæa.			
13	55	Knee painful and creaks on movement.	Marked pyorrhoa.			
14	53	Has had gouty symptoms in fingers. Slight eczema. Right shoulder and arm have been painful for one year.	Very marked pyorrhæa.			
15	50	Fall on right shoulder five weeks ago. Muscles wasted, much creaking.	Pyorrhæa.			
16	62	Rheumatoid arthritis of right shoulder.	***			
17	60	Sciatica. Rheumatoid arthritis of right hip.	Very bad pyorrhœa.			
18 .	44	Pain in right shoulder since a fall. Rheumatoid arthritis.	Pyorrhœa.			
19	2 6	Right shoulder painful and creaks.	Bad pyorrhæa.			
20	42	Rheumatoid arthritis in several joints for some years.	Pyorrhea.			
21	26	Rheumatoid arthritis, specially in fingers and elbows. Much deformity.	Acute tonsillitis 18 months ago.			
22	65	Neuritis in right arm, knees stiff and painful, crackling on movement.	Marked pyorrhæa.			
23	37	Always having rheumatic pains. Left knee painful, crackling on movement.				
24	61	Lumbago. Sciatica. Joints creak on movement.	"			
		Various Allied Disorders.				
25 :	113	Rheumatism in ankle. Occasionally complains of "rheumatics" in calves.	Tonsils septic.			
26	25	Stiffness of right side of neck.	Hypertrophic rhinitis.			
27	38	Sciatica and lumbago.	Pyorrhea.			
28	48	Rheumatism and sciatica. Neuritis in right arm.	Very bad pyorrhæa.			
29	34	Rheumatism in right shoulder.	Pyorrhæs.			
30	58	Neuritis. Rheumatism in arms and knees.	"			
31	50	Lumbago and neuritis.	11			
32	44	Rheumatism.	Bad pyorrhœa.			
33	32	Neuritis and sciatica. Acute lumbago.	Pyorrhoa.			
34	33	Sciatica, repeated attacks.	Enlarged and septic tonsils.			
35	46	Lumbago, sciatica, and neuritis.	Pyorrhea.			
3 6	50	Rheumatism for many years. Sciatica.	Bad pyorrhoa.			
37	56	Rheumatic pains in fingers and joints.	Pyorrhea.			
38	29	One attack of (?) gout at 13. Occasional muscular rheumatism. Tonsillitis 14 days ago.	"			
39	57	Pains in arm and shoulder of right side for three months. Several quinsies.	Very bad pyorrheea.			
40	36	Rheumatism in wrist two years ago. Temperature 100°2° F. Laid up for a fortnight.	Bad pyorrhoa.			
41	32	Rheumatism and lumbago.	,,			
42	45	Has always been rheumatic. Sciatica of the right leg.	••			

were removed. Subsequently the remaining teeth, with the exception of the lower canines, which were fairly firm and could be kept clean, were extracted also. No other treatment was adopted. As a result, all the symptoms originally complained of disappeared. A temporary denture was given in the last week in August, with which he was able to eat well. In October he had gained a stone in weight.

Case 3.—The patient, a married woman, aged 60 years, had very bad attacks of muscular rheumatism and lumbago, with great difficulty in walking. She suffered from anæmia and there was general weakness. She was very susceptible to influenza, which usually lasted about three weeks. As to local sepsis, there was very bad pyorrhæa, only 15 teeth remaining. Six visits were made for cleansing, during which time the general health improved. All the teeth were removed in February except the lower canines. As a result there had been no rheumatism since, while there was a gain of one stone in weight.

Case 4.—The patient, a man aged 40 years, had rheumatism in the right shoulder and was unable to play golf in consequence. He had had electrical treatment for a year. As to local sepsis, there was bad pyorrhea, although the mouth was carefully kept. It was non-purulent in type, but with many pockets between the molars. Four visits were made of 14 hours each. The last visit was in June. In October the patient wrote to say that he has had absolutely

no pain since the last treatment.

These cases are quoted to show that in certain cases cure is possible. We do not wish to suggest for a moment that the same result will occur in all, but the larger number of our cases have shown such definite improvement that we feel sure that early recognition of the source of infection is the main factor in the achievement of success. By more careful attention to the points that we have mentioned, either as a routine of life or on the first symptom of an attack, we feel sure that the number of cases of these illnesses could be limited to an extraordinary extent. It is much to be hoped that the younger generation of dental surgeons will realise that their art is not purely a mechanical one, but that they can do much towards preserving their patients from the so-called gouty and rheumatic diatheses. At present we have not succeeded in establishing a connexion between the types of pyorrhœa and the nature of the accompanying disease.

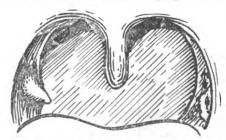

Clinical Rotes :

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ABNORMALITY OF THE RIGHT TONSIL.

By Norman Patterson, M.B., Ch.B. Edin., F.R.C.S. Eng., assistant surgeon at the hospital for diseases of the throat, nose, and ear, golden-square, etc.

THE patient, a woman aged 45 years, came to the hospital complaining of a peculiar appearance which she had accidentally noticed in the throat. She had never had any discomfort. She had been subject to epileptic fits, but never

remembered having had any pain or hæmorrhage from the throat after recovering consciousness. On examination a pointed process was seen projecting downwards and inwards from the right tonsil, as is shown in the accompanying illustration. When palpated it was felt to be a bony projection tipped with cartilage. It could be traced

upwards towards the point at which the styloid process takes origin from the skull. On the left side, although no projection could be seen, what was evidently an elongated styloid process could be felt on pressing the tonsil outwards. The illustration shows both styloid processes to be abnormally long. It is difficult to say whether the condition is congenital or due to a fracture of the right styloid process having occurred during an epileptic seizure.

Queen Anne-street, W.

EYELASH AS A FOREIGN BODY IN THE ANTERIOR CHAMBER.

BY J. B. PIKE, M.R.C.S. Eng., L.R.C.P. EDIN., HONORARY SURGEON TO THE LOUGHBOROUGH GENERAL HOSPITAL.

A BOY, aged 13 years, attended as an out-patient at the Loughborough Hospital on May 6th, 1907. A small healed wound was found at the outer edge of the cornea of the right eye. There had been slight reaction, but this was subsiding, the injury being a fortnight old. A dark line was seen lying obliquely across the pupil and inner part of the The ophthalmoscope showed this to be a foreign body. The boy stated that the injury was caused by a branch of a hedge swinging back and striking the outer part of his eye. I thought some small thorn spicule might have penetrated. On the following day with general anæsthesia I made a small incision at the inner sclero-corneal junction with a Graefe knife, and by means of an iris hook and forceps removed the foreign body. At the same time a small iridectomy was done. The foreign body under a low microscope power proved to be an eyelash. Two years after this the vision is found to equal 6/6, with or without a small correction for hypermetropia and astigmatism.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Exhibition of Specimens.—Rupture of the Uterus.— Leukoplakic Vulvitis.

A MEETING of this section was held on Nov. 11th, Dr. H. MACNAUGHTON-JONES, the President, being in the chair.

Dr. A. E. GILES showed: (1) A specimen of Ovarian Adeno-Carcinoma weighing 18 pounds, removed from a widow aged 60 years; and (2) a case of Kraurosis of the Vulva of an advanced type, in which a small nodule of carcinomatous growth was just beginning.

Dr. T. G. Stevens showed a specimen of Adeno-Myoma of the Vaginal Wall, consisting of two tumours, one situated on the anterior and the other on the posterior vaginal wall. Both contained cystic spaces lined by columnar epithelium, and he thought from their position and structure that they must be derived from displaced Wolffian tubules. He also showed a specimen of Fibromyoma and Pregnancy with extensive thrombosis of all the veins of the capsule and

necrobiosis of many areas of the tumour.

Mr. H. J. Paterson read a short communication on a case of Rupture of the Uterus treated by suture of the rent per vaginam and drainage. The patient, a iii.-para, after premature rupture of the membranes was found to have a prolapsed pulseless cord. Delivery was effected by traction on the foot without difficulty, but on introducing the hand into the vagina after delivery it passed into the abdominal cavity. On admission to the Temperance Hospital the patient was profoundly collapsed. The vagina was full of blood clot, and a coil of intestine was felt protruding through a large rent in the vaginal vault, through which the fist could be easily passed into the peritoneal cavity. The left parametrium was involved in the tear, and there was free bleeding from two large vessels. These were secured by ligature. Further examination showed that the cervix and lower uterine segment were torn through for four inches, but as the uterus appeared firmly retracted no attempt was made to define accurately the upper limit of the tear. The torn edges of the cervix and

lower part of the uterus were approximated by three catgut sutures. A large rubber drainage-tube was passed into Douglas's pouch and the torn edges of the peritoneum and the vaginal wall were drawn together round it by a purse-string suture. The patient was much collapsed at the end of the operation, but continuous saline proctolysis was maintained for 60 hours, and she ultimately made a good recovery. Mr. Paterson said, as far as he knew, this method of vaginal suture and drainage had not been adopted in any of the recorded cases of rupture of the uterus. He thought that some writers laid too much stress on the difficulty of controlling hæmorrhage and nature's ability to deal with internal hæmorrhage. Suture when possible was to be preferred to hysterectomy, and the cases recorded seemed to show that some of them had recovered in spite of hysterectomy rather than on account of it.

Dr. COMYNS BERKELEY and Dr. VICTOR BONNEY read a paper on Leukoplakic Vulvitis and its Relation to Kraurosis Vulvæ and Carcinoma Vulvæ. The authors pointed out that leukoplakia and kraurosis were two distinct diseases, which could be identified quite easily both from clinical observation and a pathological examination of the tissues affected. The authors based their paper on the series of 24 cases which they had operated upon and 75 which had occurred in the practice of their colleagues at the Middlesex Hospital and Chelsea Hospital for Women. The authors pointed out that leukoplakia can be differentiated clinically from kraurosis: 1. By its appearance, which is quite different from that of 2. By its distribution, in that it never affects kraprosis. the vestibule, orifice of the urethra, or vagina, whereas in kraurosis these areas are always affected; and whilst in the latter disease the outer surface of the labia majora and the skin of the thighs and the perineum in their neighbourhood are never affected, in the former disease it is often involved. 3. By the symptoms, for whereas the striking and often the only symptom of leukoplakia is pruritus, this symptom is absent in kraurosis, whilst dysuria and dyspareunia are most marked. 4. By its relation to carcinoma. Leukoplakia is often followed by carcinoma of the vulva, and in every case of this disease which the authors had seen leukoplakia had been present, whilst kraurosis had no relation to carcinoma. 5. By its histological findings. It will be seen that in leukoplakic vulvitis there occurs a diffuse thickening of the epithelial elements with a marked tendency to downgrowth, as exhibited by long interpapillar processes. The underlying connective tissue is at first the seat of a lymphocytal aggregation, which leads on to a diffuse fibrosis with a total disappearance of yellow elastic fibres in the zone immediately underlying the epithelium. In kraurosis the epithelium is abnormally thin, especially over the red patches seen in that disease. Polymorphonuclear leucocytes and massive aggregations of plasma cells are seen, whilst lymphocytes are comparatively sparsely represented. The connective tissue becomes the seat of an atrophic shrinkage, but except at the points of massive plasma cell proliferation, no disappearance of the yellow elastic tissue occurs. The authors lastly discussed the relationship of leukoplakia to carcinoma, including multiple carcinoma of the vulva, recurrences of the growth, and glandular metastases. With regard to treatment, the authors were strongly of the opinion that all the cases of leukoplakic vulvitis should be treated by excision, because this disease in their experience had been so commonly followed by carcinoma. The paper was illustrated by a series of micro-photographs demonstrated by the epidiascope. Dr. GILES said that there was no evidence in any case of kraurosis which had come under his notice of a history of either syphilis or tubercle, but he regarded the condition as an atrophic one incidental to the general atrophy affecting the pelvic organs at the menopause. Dr. AMAND ROUTH agreed that the authors had brought forward very strong arguments in favour of their contention that leukoplakia and kraurosis vulvæ were essentially distinct conditions, capable of easy clinical differentiation. If their contention were correct all modern text-books were wrong, for without exception they described the two conditions under one name-kraurosis vulvæ. According to the authors, in leukoplakia, pruritus was the main, often the only, symptom, neither the vestibule nor the urethral orifice was ever attacked, but the disease tended to spread over the inner thighs, perineum and anus, and there was no tendency to contraction of the vaginal orifice.

Epithelioma of the vulva very often followed this condition. In kraurosis vulvæ, on the other hand, there was no pruritus. and dyspareunia was the main symptom. The vestibule and urethral orifice were always attacked, the thighs, perineum. and anal region never. The vaginal orifice always became contracted, and carcinoma never developed on the vulva in kraurosis. He described a case, however, to prove that if leukoplakia and kraurosis were not two stages of the same disease, they sometimes co-existed. As regards treatment. he had found that the continued application of equal parts of unguentum hydrargyri and unguentum zinci or unguentum plumbi acetatis almost always relieved the pruritus and made the tissues softer and pinker, but the condition was apt to recur. He had not seen any case with a definite history of syphilis. -Dr. T. W. EDEN said that there was nothing inherently improbable in the idea that leukoplakia was a condition antecedent to epithelioma, for this sequence had been recognised for long in the tongue. He could hardly follow the authors in their recommendation to excise all patches of leukoplakia, since this condition was not at all uncommon, while the malignant transformation described in the paper was comparatively rare.-The PRE-SIDENT said that the last edition of his text-book was open to the criticism of Dr. Routh, for although the views of many authorities were epitomised, there was no mention of leukoplakia. The two conditions were dealt with under the one term, kraurosis. His experience led him to regard discharge—both uterine and vaginal, and senility, as important factors in the etiology. No patient he had treated had he known to suffer from carcinoma subsequently. He believed in free excision of the "washleather" areas, though not to the exclusion of other therapeutic measures such as the application of pure carbolic acid and the use of a 5 per cent. solution of nitrate of silver. He also recommended adrenalin, the use of lanolated ichthyol ointment, and yellow oxide of mercury, with emollient baths, followed by the application of the nitrate of silver. He quoted two cases cured by excision and transplantation of sound skin, combined with the use of the remedies mentioned. He believed that while nothing save excision would suffice in certain cases, yet in others cure could be effected without resource to this severe measure.—Dr. BERKELEY, in reply, said that the discussion of the paper had mainly had reference to two points—namely, the ease or otherwise of the diagnosis of these two conditions and the question of the treatment of leukoplakie vulvitis by excision. In reality the two diseases were easy to diagnose, and it was their marked difference which had drawn his and Dr. Bonney's attention to this subject. With regard to treatment, they were convinced that the proper treatment was to excise the diseased areas. He had had the unusual experience of operating upon 18 cases of carcinoma of the vulva all associated with leukoplakia, and at least three of these had been subjected to prolonged treatment for the leukoplakia. He saw no reason why leukoplakia and kraurosis should not occur in the same

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens .- Strangulation of the Small Intestine.

A MEETING of this section was held on Nov. 26th, Dr. J. PORTER PARKINSON being in the chair.

Dr. A. E. GARROD showed a case of Multiple Peripheral Neuritis in a girl, aged 8 years, who was quite healthy until March, 1909, when she passed involuntarily a stool containing several ounces of blood. This was preceded by an attack of abdominal pain. A similar attack occurred in May, and several others later. When admitted to hospital on Sept. 16th she was a well-nourished child; good mental condition; marked loss of power in both upper limbs from deltoid downwards, and double wrist drop; muscles of lower limbs weak; no tremor; sensation unimpaired; other systems normal. Electrical reaction showed muscles of all extremities with reaction of degeneration (except flexors and special muscles of thumb and little finger). Blood examination: red corpuscles, 4,984,000; hæmoglobin, 94 per cent.; white cells, 10,500. No cause for the condition was discoverable. -Dr. G. A. SUTHERLAND regarded the case as one of special interest, and thought a certain positive diagnosis was not possible.—Dr. E. I. SPRIGGS referred to two similar cases shown at the last meeting.

Dr. ROBERT HUTCHISON showed two cases, one a Female Child, aged 9 years, with Cirrhosis of the Liver. There had been swelling of the abdomen for one year; no previous illness of importance. Two still-births preceded this child. There were snuttles as a baby. The liver was enlarged and irregular, and the spleen considerably enlarged. There was some ascites; the child had a cirrhotic facies. Dr. Hutchison took the view that the condition was due to syphilis and stated that a positive Wassermann reaction had been obtained. The other case was one of Unidactyly in a male, aged 13 weeks. The small digit only was present on both hands and both feet. The child was otherwise normal. The child's father, two uncles, and an aunt were similarly affected, as also the grandfather and his brother. A daughter of the father's sister also exhibited the condition.—Dr. PARKINSON, Dr. C. W. CHAPMAN, Dr. SUTHERLAND, and Dr. GARROD discussed the cases.

Mr. O. L. Addison showed a case of Congenital Enlargement of One Limb occurring in Brother and Sister, aged 9 and 5 years respectively. The boy's arm, shoulder, and hand were enlarged, and there was one inch increase in length. In the girl the enlargement was in the left leg, which was an inch and three-quarters increase in length. The calf was relatively larger than the thigh, and was hotter than the rest of the limb.—The cases were discussed by Dr. F. PARKES WEBER, Mr. J. P. L. MUMMERY, and Dr. GARROD.

Dr. R. C. JEWESBURY exhibited a specimen of an Infantile Heart showing Nodules on the Endocardium. The specimen was from a child, aged 4 months, who died from bronchopneumonia. No cardiac lesion was detected during life. Post mortem, a large number of wart-like nodules were found, especially on the mitral and aortic valves, a few also on the other valves and on the septum of the foramen ovale. Microscopical sections through the nodules showed a connective tissue substratum supporting a layer of epithelium. There were no signs of recent or previous inflammation. There was nothing to suggest that the nodules were "vegetations,"and it was stated that the condition occurred normally in the infant heart.—Dr. SPRIGGS regarded the nodules as hypertrophy of the little nodules usually seen in infants' hearts.

Dr. H. D. ROLLESTON (for Dr. CARPENTER) exhibited a specimen of Compression of the Trachea by the Enlarged Thymus. The specimen was removed from a child, 10 months old. who died after an illness of less than 24 hours, which began with quick breathing and sickness. The temperature reached 103°F. and the respiration rate 80. During life there were recession of the intercostal spaces and embarrassed breath-The specimen showed a large thymus pressing on the trachea, which was much narrowed from before backwards. The lungs showed evidence of death from asphyxia. The liver and spleen showed some fatty change but the other organs were normal. The case was shown as positive evidence that an enlarged thymus may cause death. He also showed a Microscopical Section from the Liver of a case of Icterus in an infant. The specimen showed a normal condition of the liver.

Mr. MUMMERY read a paper on a case of Strangulation of the Small Intestine by a Band in a child, aged 15 months. The child had acute obstruction, which developed suddenly, and was operated upon within nine hours of the onset of symptoms. A tumour, which was thought to be an intussusception, was distinctly felt in the right side of the abdomen. The child had been operated upon for intussusception when five months old. On opening the abdomen a loop of small bowel was found acutely strangulated by a narrow band. The band was divided and the abdomen closed. The child made an uninterrupted

HARVEIAN SOCIETY OF LONDON.

Discussion on Angina Pectoris.

A MEETING of this society was held on Nov. 25th, Dr. C. BUTTAR, the President, being in the chair.

Dr. ALEXANDER MORISON read a paper on the Nature and Treatment of Angina Pectoris. He remarked that if the term were used comprehensively as applying to all forms of cardiac pain the condition was not rare, but if limited to classical cases, usually without valvular disease, he could had never seen a case. Dr. Morison, however, would treat pathology of angina pectoris was properly understood.

the condition more comprehensively, and defined angina pectoris as a painful affection of the heart as a whole, dependent upon disorganisation in the anatomical character or disorder in the physiological function of one or more of the factors in cardiac action, and associated in some cases with a fear of impending death. He gave a short abstract of 10 cases as supplying the data upon which he rested his conclusions regarding the nature of the affection, instancing cases both of dextral and sinistral radiation of the pain. The conclusion he arrived at was that the character and situation of the conditions which originate angina vary, and that the heart, if like other viscera, endowed with low sensibility to handling and other modes of external irritation under normal circumstances, may, in the presence of lesion of its internal surfaces or severe stimulation of its nervous endowment by compression or otherwise, reveal evidences of sensibility as well marked as do other viscera in their interior under circumstances which may be regarded as analogous. He argued that even the commencement of referred pain in a peripheral portion, such as the arm, in no way invalidated the belief that intra-aortio or intracardial nerves were not also the seat and site of referred pain. In speaking of treatment, he divided his remarks into a consideration of the treatment (1) of the attacks, and (2) of the conditions which provoked the attacks, and pointed out that the majority of cases of so-called vaso-motor angina with valvular disease tended to subside without accident so far as the attack was concerned. This was not so with non-valvular cases, which might rapidly terminate fatally, and required, not merely the use of nitrites, but also of morphia, atropine, and general anæsthesia for relief and to avert death. At the close of his remarks Dr. Morison showed a patient upon whom thoracostomy had been performed with benefit for cardiac pain. An account of this case has already appeared in THE LANCET of July 4th, 1908, and Nov. 20th, 1909.

Sir CLIFFORD ALLBUTT said that to properly understand the nature of angina pectoris it was necessary to consider cases that were not complicated. He considered that the cause of uncomplicated cases of angina pectoris was disease of the aorta above the valves, and he thought that the distribution of the radiating pain depended largely on the part of the aorta affected. He thought that there was a pain arising from the heart itself, and situated in the præcordial area, which was quite distinct in character from the pain of a typical anginal attack. He insisted on the importance of early specific treatment in cases of angina pectoris.

Sir R. Douglas Powell considered that cases of typical angina pectoris were due to atheroma and thrombosis of the coronary arteries. He would not class as "angina' mere aortic pain following exertion. He considered rise of arterial blood pressure an important factor in the causation of angina pectoris, and gave instances of cases in which the development of mitral regurgitation had caused relief from anginal attacks.

Sir LAUDER BRUNTON thought that the pain of angina pectoris was partly due to contraction and he compared the pain to the contraction of a distended bladder. He considered that there was a sensory nerve-supply to the heart, and cited the results of experiments on animals in support of this. He thought that the pain of angina pectoris was due in some cases to increase of arterial blood pressure; in other cases spasm of the coronary arteries was an important factor. He laid stress on the importance of careful regulation of exercise in angina pectoris and also on the advisability of rest after a meal.

Dr. JAMES MACKENZIE thought that the symptoms of angina pectoris should be carefully understood and that the distribution of the pain should be carefully investigated. He thought that irregularities of the heart were important, and also that great exhaustion of the heart muscle was usually present in anginal attacks.

Dr. D. B. LEES said that many of the attacks of so-called angina pectoris were not really typical. He thought that a very important confirmatory physical sign was a dilated aorta, and emphasised the importance of a careful examination by percussion. He considered that excessive indulgence in tobacco-smoking was a very important factor in the causation of angina pectoris. He said that investigation of the nerve understand the fact mentioned by Stokes of Dublin that he plexuses about the aorta was very necessary before the

Dr. E. H. COLBECK considered that "pain in the heart" was the main factor in the symptoms of an anginal attack. He thought that any theory of explanation of the condition must account for the fear of impending death.

Sir JOHN BROADBENT said that there was a great deal still to be learnt about the etiology and pathology of angina pectoris. He thought that most attacks were due to a spasm of the vessels induced by cold and exertion.

Dr. W. BEZLY THORNE thought that distension of the heart was the true cause of angina pectoris. He spoke of the presence of tender areas at the apex beat, over the third left costal cartilage, and over the lower part of the sternum. He advocated the use of blisters here in the treatment of the condition.

Dr. W. EWART considered that the influence of respiration on angina pectoris was not sufficiently taken into account. He thought it was possible that spasm of the diaphragm might in certain cases account for some of the pain present in an anginal attack.

NORTH LONDON MEDICAL AND CHIRURGICAL Society.-A meeting of this society was held at the Great Northern Central Hospital on Nov. 11th, Dr. James Crabb, the President, being in the chair.—Dr. Thomas J. Horder showed a case of Hæmophilia occurring in a child, aged 19 months, who had shown a tendency to bleed excessively since birth. The parents, who were first-cousins, showed no history of hæmophilia on either side. The patient had one brother and one sister, the latter, aged four years, being a hemophiliac.—Mr. G. B. Mower White showed a case of Hæmophilia, the patient being a boy, aged 13 years, who had been admitted to hospital with a swelling of the knee-joint of four months duration. The swelling had come on after a slight twist, and was found to consist of blood-stained synovial fluid. The blood when withdrawn did not coagulate for three-quarters of an hour, and the clots which were formed were small and shreddy. The boy was not anemic and his blood-count was It was stated that when he was an infant a cut on his head bled for three weeks, and that after the extraction of a tooth he continued to bleed for a week. He had had occasional attacks of pain and swelling of both knee-joints, and it had been noticed that he bruised quickly and over a large area after a blow. His family history showed nothing of interest.—Dr. C. M. Hinds Howell showed, for Dr. Horder, a case of Atrophy of Some of the Muscles of the Neck in a child, aged 7 years. The condition had begun a year ago during an acute attack of tonsillitis. The sterno-mastoids and trapezii were wasted and there was weakness of extension and rotation movements. Passive movements were fairly free. There was cervical scoliosis with the convexity to the left, and a skiagram by Dr. Lewis Jones showed a slight malposition of the axis with regard to the atlas. On attempting to rotate the head or to open the mouth widely the platysma was thrown into strong contraction. There was no wasting or weakness of the muscles of the extremities, and all the deep reflexes were present though diminished. There were no electrical changes in the mastoid muscles. -Dr. Hinds Howell and Dr. T. J. T. McHattie showed a woman who had been under observation for nine months suffering from Cerebral Symptoms of a Mixed Functional and Organic Nature, such as rendered a diagnosis of the actual lesion a matter of great difficulty. There had been constant headache, sickness, and giddiness, which had persisted in spite of treatment since last December, and had followed a blow on the head from a saucepan. Combined with these symptoms there were nystagmus, tinnitus, and nerve deafness on the right side, and complete loss of the power of smell and taste on the same side. The patient complained of almost total blindness in the right eve. though both disc and fundus were normal. and when tested with a prism applied to the right eye she was found to have 6/18 vision and to see double. There was distinct weakness of the lower facial muscles on the left side and of the muscles of the limbs on the right side. There was right partial hemianæsthesia, crossing the middle line by about 1 inch, as well as loss of sense of position of the limbs. Her reflexes were brisk, the plantar reflex on the left side was flexor, while that on the right side could not be obtained. Her gait at present was normal, though there had been a tendency to drag the right foot. When standing with her eyes shut she

tended to fall to the left. Dr. Howell was of opinion that the symptoms were mostly of a functional nature, though he thought that a tumour in the right temporosphenoidal region might account for the deafness and the loss of power on the left side of the face. -Mr. Mower White said that the case reminded him of a man whom he had seen some years ago, and who was found wandering about, anæsthetic on the left side, and unable to speak. He was sent into a lunatic asylum. The functional nature of his complaint was discovered when it was found that, his right hand being held, he was able to button up his coat with his left anæsthetic hand. Playing in a cricket match he was bowled with the first ball, exclaimed "D—," and from that moment was well.— Dr. McHattie showed a man, aged 63 years, in whom there was Motor Aphasia, combined with paralysis of the face, arm, and hand, and partial paralysis of the leg on the right side. The patient was able to repeat one or two familiar words, could sing in correct time, could read, and, though somewhat dull mentally, was obviously able to understand what was said to him. The onset had been gradual, and Dr. McHattie thought that it had probably been caused by a thrombosis of the middle cerebral artery, involving the cortex in the region of Broca's convolution. - Other cases and specimens were shown by Dr. B. G. Morison and Mr. Ernest H. Shaw.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCO-LOGICAL SOCIETY.-A meeting of this society was held at Sheffield on Nov. 19th, Dr. J. W. Martin (Sheffield), the President. being in the chair. -Dr. A. Donald (Manchester) read notes of a case of Wertheim's operation for Advanced Cancer of the Cervix, which was followed by uramia. 4 ounces of urine were passed on the first two days, and none at all on the third; on the fourth and fifth 62 and 120 ounces respectively were passed, and the patient appeared to be making good progress. On the sixth day coma set in, and death occurred a few days later. At the post-mortem examination the right kidney was found to be the seat of old cystic disease and to contain but little secreting tissue, whilst the left ureter had been constricted by a ligature. The left kidney was engorged but appeared to have been healthy before the operation -Dr. H. Briggs (Liverpool) recorded a case in which he had removed a Pyosalpinx, on account of pelvic pain of a month's duration, from a 2-gravida who was two months pregnant. The operation was performed three weeks ago, and the pregnancy was apparently undisturbed. Dr. Briggs also gave the details of a case of old-standing, Left-sided Pyosalpinx, for which the patient had refused operation three years previously. She improved and bore two children, but during the last nine months several attacks of pelvic pain had occurred. Recently the left ovary and the tube, which contained pus, had been removed.—Mr. Percival E. Barber (Sheffield) read the notes of a case in which he had performed total abdominal hysterectomy for Placenta Prævia Centralis. The patient, a 4-gravida, had been losing blood for a week before admission to hospital. Vaginal examination caused profuse hæmorrhage, which necessitated plugging the cervix and vagina. When Mr. Barber saw the patient she was blanched and apparently moribund; the pulse-rate was 140. The uterus. containing a dead full-time child, was removed. Two pints of saline were infused intravenously. The patient made a good recovery.—The following specimens were shown: -Dr. D. Lloyd Roberts (Manchester): A Uterus which he had removed for Malignant Disease of the Corpus. It was found to contain a fibroid polypus the base of which was invaded by glandular carcinoma arising from the neighbouring endometrium. The apex of the polypus was quite free from malignant disease. The patient was a multipara, aged 65 years, who had ceased to menstruate at 50 years. For three months there had been almost constant hæmorrhage, with, on three occasions, floodings accompanied by severe pain.—Dr. J. E. Gemmell (Liverpool): A Sarcoma of the Mesentery which clinically had simulated an ovarian cyst with long pedicle.—Dr. W. E. Fothergill thought the microscopical appearances were those of a perithelioma. -Mr. R. V. Favell (Sheffield): A round cell Sarcoma of the Vagina, removed from a single woman, aged 25 years. The hard nodular growth was easily enucleated and removed with its covering of vaginal wall.—Mr. P. E. Barber: A full-time Ectopic Gestation Sac, which had been successfully removed from a multipara, aged 34 years. Soon after the commencement

of the period of nine months' amenorrhœa she had experienced a sudden attack of right-sided pelvic pain with a feeling of faintness; this was not accompanied by external hæmorrhage. The fœtal movements, which had been very violent and painful, had ceased six weeks before admission. There was no history of spurious labour pains. The sutures of the softened feetal head could be easily felt through the thin abdominal wall and the state of affairs was readily diagnosed. The sac, which was largely extra-peritoneal, was removed entire with the body of the uterus, to which it was intimately united. The left appendages were normal. The right could not be discovered either at the operation or on later examination of the specimen. The right round ligament ran into the sac. The placenta, greatly thickened by blood clot, was attached to the back of the uterus and to the tissues at the base of the right broad ligament. - Mr. Barber also showed a Uterus with a Right Tuberculous Pyosalpinx and a Left Tuberculous Tube-ovarian Swelling. A nodule of caseating material enlarged the right angle of the uterus around the interstitial portion of the tube.—Sir William J. Sinclair showed Long Sea-tangle Tents suitable for the induction of labour. The tents were six or seven inches in length. Similar ones had already been used with good results in several cases.

MIDLAND MEDICAL SOCIETY .-- A meeting of this society was held on Nov. 17th, Mr. Frank Marsh, the President, being in the chair.—Mr. William Billington showed a child, $2\frac{1}{2}$ years old, all of whose nails resembled claws. The child was the sixth of a family of seven, the rest of whom were normal. The family history was negative. The fingers and toes were perfectly natural and showed no trophic disturbance. Each nail closely resembled the claw of a dog, being raised, almost black in colour, very hard, and projecting some distance beyond the extremity of the digit. - Mr. C. A. Leedham-Green showed a young woman with a large intermittent Hydro-nephrosis of the Right Kidney. Some six years previously the left kidney was removed for advanced pyo-nephrosis. At that time there was no evidence of any trouble on the right side. Gradually a hydronephrosis had developed in the remaining kidney and was slowly destroying it. The pressure of the fluid was causing such atrophy of the glandular tissue that signs of renal inadequacy were becoming manifest. A radiograph was shown, clearly indicating the size and relation of the cystic swelling. For the purpose of the radiography a catheter had been passed up the ureter and the cyst distended with a solution of collargol.—
Dr. O. J. Kauffman showed a case of Syringomyelia of seven years standing in a girl aged 15 years. The symptoms were muscular atrophy of the right hand, forearm, and deltoid. and spastic paralysis of the legs, left hemianæsthesia up to the level of the third cervical segment, coupled with hemianalgesia and thermanæsthesia in the same area. Tactile anæsthesia, analgesia, and thermanæsthesia were present in the right arm, though the right leg and the right half of the trunk showed no distinct anæsthesia. The right pupil and palpebral fissure were smaller than the left, and there was very marked kyphosis of the cervicodorsal region coupled with scoliosis below. No trophic joint lesion was present, but there was a great tendency to almost painless sores on the right limbs and the right buttock. The onset and progress were absolutely gradual and without the slightest history of pain at any time.— Mr. F. Victor Milward showed a case of Rupture of a Branch of the Superior Mesenteric Artery in a man aged 49 years. The hæmorrhage was excessive but the pulse-rate was never more than 70. Great difficulty was experienced in locating the torn vessel, and five pints of normal saline solution were infused into the internal saphenous vein. Ultimately recovery was uneventful. -Dr. Smallwood Savage showed a large Hydrocephalic Feetus which had caused an obstructed labour. The patient was admitted into the Birmingham Maternity Hospital with the body and limbs of the feetus hanging outside the vulva, but the large head, reaching 3 inches above her unbilicus, obstructing the complete delivery. An incision was made over the cervical spine, a trocar and cannula were inserted into the brain, and 3 pints of cerebro-spinal fluid were withdrawn. The collapsed head was then delivered with ease .- Dr. Thomas S. Short showed a specimen of a Thoracic Aortic Aneurysm with a sac measuring 6 inches by 5, taken from a man aged 56 years. It had exerted pressure on the

trachea and œsophagus and eventually caused death by rupture into the right pleural cavity. The acute symptoms had existed for ten days only, and throughout the whole history of the case there had been a complete absence of pain.—Mr. J. Hall-Edwards exhibited a new apparatus for electrical treatment and massage (netama). Its chief novelty consisted of an interrupter which could be regulated to make and break the current at measured intervals. It was claimed that the current was directed more deeply into the tissues than usual and that the muscle-contractions were stronger. The strength of the current could be regulated with precision.—Other cases and specimens were shown by Dr. J. G. Emanuel, Dr. J. E. H. Sawyer, Dr. J. Douglas Stanley, Dr. Charles E. Purslow, and Dr. H. Beckwith Whitehouse.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.-A meeting of this society was held on Nov. 5th, Mr. A. E. Maylard being in the chair.—Dr. W. S. Syme showed a patient with Polypus of the Vocal Cord. Dr. S. J. Cameron described an operation devised to facilitate the Removal of the Appendages in Chronic Salpingitis, and showed illustrative drawings.—Mr. H. Rutherfurd showed three interesting specimens illustrative of Gangrenous Hernia from cases of Richter's Hernia, Inguinal Hernia, and Obturator Hernia.-Dr. G. A. Allan read notes on two cases of Dextrocardia. The first was the case of a patient suffering from mitral disease, in whom it was found that the apex beat was situated in the sixth interspace, seven inches to the right of the midsternum. The liver, stomach, and spleen were found to be likewise transposed. The patient died, and at the necropsy a transposition of the viscera implicating the thoracic and abdominal organs in every detail was found. The second case was that of a patient with left hæmopneumo-thorax, in whom the cardiac dulness and pulsation were found to be displaced to the right of the sternum. patient recovered, and in six weeks the heart had regained its normal situation. The cause of the hæmopneumothorax was not obvious. There had been no injury and no evidence of phthisis or other pulmonary disease could be discovered. The condition came on suddenly when the patient was enjoying apparently good health.—Dr. W. K. Hunter showed Blood Films from a case of Acute Hæmorrhagic Leukæmia. The patient, a woman, aged 22 years, dated her illness from a bleeding from the gums four weeks previously. A fortnight later blood appeared in the urine and had persisted. There was no history of blood in the motions or of bleeding into the skin. On admission to hospital the patient looked very ill; the temperature was 100° F., the pulse was 120; the skin and mucous membranes were pale; there was bleeding from the gums; the breath was offensive; there were a few bluish markings on the skin like slight bruise marks; the urine resembled blood serum. There was no enlargement of the liver, spleen, or lymphatic glands; the heart apparently was normal; there was slight dulness at the left base, with scanty moist rale; no expectoration. Blood condition: red corpuscles, 2.680,000; white corpuscles, 59,375 per cubic millimetre; hæmoglobin, 45 per cent.; a little poikilocytosis; many nucleated red cells, about 2 per cent. of white cells. The great majority of the white cells were medium-sized mononuclear cells with fairly well stained nucleus and less deeply stained plasma. In a proportion of these cells (with Leishman's stain) the plasma had a rather leaden tint; in others were granules stained the same tint as the cell nucleus. In films stained with methylene blue only these granules stained blue. There were no typical "large lymphocytes "-i.e., cells with large pale nucleus and rim of darker stained plasma—only an occasional neutrophile marrow cell. Differential count: polynuclear cells, 4 per cent.; small lymphocytes, 15 per cent.; mononuclears, 79 per cent.; neutrophile marrow cells, 2 per cent. The patient lived eight days after this blood count, having been ill apparently about five weeks in all. Of special interest in the case were: (1) the hiematuria, a rare symptom in leukæmia; (2) the preponderance of mononuclear cells, which were neither typical large lymphocytes nor neutrophile marrow cells, a feature which made it doubtful whether the case should be classed as a lymphatic or a myelogenous leukæmia. Dr. Hunter referred to a similar case reported by Fiessinger and Pierre-Louis Marie in La Tribune Médicale of Jan. 16th, 1909. Dr. J. Wyllie Nicol showed Wax Casts made from patients suffering from various skin diseases. The casts were

made with the assistance of Mr. A. Kirkpatrick Maxwell, who did the colouring.

United Services Medical Society.—A clinical meeting of this society was held at the Royal Army Medical College on Nov. 10th, Sir Alfred Keogh, K.C.B., Director-General, A.M.S., being in the chair. — Captain C. C. Cumming, R.A.M.C., showed a case of Heat Stroke invalided from India. The onset was sudden and after an interval of 36 hours' unconsciousness the patient was found to be suffering from inability to speak distinctly or intelligibly or to walk or use his arms. At present there is no impairment of the general functions or of sensation. His speech is slow and deliberate, the words being slurred to a certain extent. There is incoordination to a slight amount in both upper and lower limbs, and he is unable to maintain his balance without some slight support. There is no loss of memory or brain power. Major W. S. Harrison, R.A.M.C. commenting on the case, remarked on its resemblance to one of disseminated sclerosis, from which, however, it differed in the steady improvement that it showed. He pointed out that the man was not conscious of any impedient to his speech, a symptom that was present even when the speech was quite unintelligible.—Captain Cumming then showed a case of Splenic Anæmia. The patient had been invalided on account of enteric fever in 1902, and the enlargement of his spleen dates from that period. Towards the end of that year he had an attack of hæmatemesis and syncope, the spleen being much enlarged. Similar attacks occurred in 1903, and again after a long period of freedom in 1907, and at the beginning of last year. At present the spleen is enlarged to within one inch of the umbilicus and is tender in the axillary line. The red cells are reduced to 3,000,000 and the hæmoglobin 50 per cent. His last severe attack of hæmatemeeis was in April last, since when there has been decided improvement.—Major Harrison pointed to the nontropical origin of the case, which was a characteristic example of Banti's disease. Malaria and kala-azar were excluded by the absence of parasites, and there was in addition none of the leukopenia so marked as a rule in the latter disease.—Captain J. C. Kennedy, R.A.M.C., described a case of Phagedenic Ulcer of the Larynx. The symptoms were not well marked as regards the larynx till within a few days of death. The previous history was one of high fever and enlargement of the liver and splcen. No parasites were present in the smears made from a liver puncture. post-mortem examination showed erosion of the tip and edges of the epiglottis, with sloughing in the region of the left vocal cord. A large bacillus was found invading the tissues at the base of the ulcers, possibly the cause of the disease. It was found impossible to subculture this organism. Resemblances were pointed out between this case and theulcerous rhinopharyngitis of Leys, as well as the sloughing phagedæna of the tropics mentioned by Manson. - Major C. G. Spencer, R.A.M.C., showed a case of Fracture of the Cervical Vertebræ, unrecognised at the time of occurrence, and only revealed by a subsequent X ray photograph 10 days after the accident. There was then some rigidity in the cervical region, but no tenderness or deformity. At present there is still some rigidity of the neck, and an area of impaired sensation on the posterior surface of the lower third of the forearm.—A discussion followed, in which Fleet-Surgeon V. G. Thorpe, R.N., and Lieutenant-Colonel R. W. Wright, R.A.M.C., took part, chiefly as to the advisability of early operation in serious cases of spinal fracture. Skiagrams of the case were

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Nov. 26th, Mr. C. Gordon Watson, the President, being in the chair.—Dr. B. G. Morison related the following three cases of Melena Neonatorum:—1. On the morning of the fourteenth day after the birth of a healthy child the diaper was found to be "full of blood," and almost immediately after the child died. The post-mortem examination showed that the gall-bladder contained some bloodclot as well as dark bile. The stomach contained bloody mucous fluid. The small intestine was entirely filled from end to end with dark bloody fluid, which escaped on puncture. The suprarenals were not distended and looked pale, but on opening them a little dark blood was found in both. Microscopically they showed extreme congestion of the medulla but no actual extravasation of blood. The capillaries in the medulla were widely dilated and the appearance suggested some possible interference with the normal blood

return from the organs. It did not suggest an acute condition, but rather one of some standing. 2. When born the child was of a dirty-brown colour, "like a penny," and the penis and scrotum were blue as if from subcutaneous hæmorrhage. There was bleeding from the cheeks; the skin was cracked in the flexures and bled easily. Brown material was vomited and black stools were passed which were occasionally mixed with a little pure blood. The child rapidly wasted and died on the twelfth day. Post mortem there was ecchymosis of the mesentery and mesenteric glands, ileum, and hepatic flexure of the colon. The suprarenals were rather larger than normal and in each there was a thin layer of dark blood in patchy arrangement. Microscopically they showed marked congestion of the medulla with blood free among the cells, infiltrating in places up to the cortex. 3. A healthy child, went on well for a week, then had hæmatemesis and passed dark "coffeeground" motions, which continued till death on the fourteenth day. Post mortem the mucous membrane of the intestine showed venous congestion from the anus up to the stomach. The suprarenals seemed rather large, and microscopically were engorged with blood. The question arose whether melæna neonatorum was merely part of a general hyperæmia which overflowed in the alimentary tract or whether it could have exercised a causal influence in the latter occurrence. Dr. W. Langdon Brewn showed some Pathological Specimens.- Mr. J. Houston Porter read notes of a case of Pneumothorax which had been twice operated on.—Dr. D. Ross read a short paper on the Relationship of Calculus to

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on Nov. 18th, Dr. L. S. McManus, the President, being in the chair.—Dr. Victor Bonney read a paper on the Prevention and Treatment of Puerperal Sepsis.—A discussion followed.

Rebiews and Aotices of Books.

Naval Hygiene. By James Duncan Gatewood, M.D., Instructor in Naval Hygiene, U.S.N. Medical School, Washington, Medical Inspector, U.S.N. Prepared by direction of the Bureau of Medicine and Surgery, and published by permission of the Navy Department. With eight coloured plates and 105 illustrations. London: Rebman, Limited. 1909. Pp. 477. Price 25s. net.

Sir John D. Macdonald's "Naval Hygiene" appeared in 1881 and Romeril's little "Sanitation in the Mercantile Marine" in 1898. No other book on this subject has recently appeared in English. It is well the lacuna should be so worthily filled as by this account of the hygiene of the United States Navy. To direct our efforts for the prevention of disease we must first know what diseases there are to be prevented, so the author first discusses the relative prevalence of the diseases which occurred in the United States Navy from 1895 to 1905. Unhappily, he rarely states the crude figures, but only ratios, so it is difficult to find out with exactly how large a mass of facts he is at any time concerned. He has evolved a very valuable method by which to express the full damage done to the service in any one year by a single disease, or by all, assembling into one number the loss of service in that group per 1000 men daily from its sickness, deaths, and invalidings all together. As the deaths and invalidings are probably distributed evenly throughout the year, and one invaliding on March 31st means 9 months lost, another on Sept. 30th 3 months lost, average for the two 6 months lost, the service loses on the average for each man dead or invalided half the work it should have got out of him. Thus the total loss of service in any one year by the deaths and invalidings is their number × 6 months = half the number × 1 year. In short, to the sick daily per 1000 add half the deaths per 1000 and half the invalids per 1000, and the sum will be the total waste in that year daily per 1000 men from whatever disease or group of diseases we are at the

moment considering. Though most valuable and a great advance, this method is not final, for invalidings are given the same weight as deaths, vastly more important though these latter are to the nation if not to the navy.

In the United States Navy the greatest loss is by venereal disease, of which it is stated that it "takes more of the strength of nations than all wars and accidents," and is "accountable for more than 25 per cent. of all the damage from disease." The importance of intoxication as a predisposing cause is noted, alcohol being "not only a sexual stimulant, but a paralyser of the inhibitory control of the will." Very successful preventive measures taken on U.S.S. Wilmington in China in 1906 are reported (p. 46). Tubercle is the next most frequent cause of loss of service (8 per cent.); it occurs mainly amongst recruits. For prevention he recommends: (1) the zealous (author's italics) search for the bacillus in sputum; and (2) the immediate removal from the ship and invariable ultimate invaliding of every case.

The second chapter, Air, is the most important in the book, as this section must be in every book on the hygiene of ships. As an example of the author's treatment of the subject we may quote (p. 195) his account of the objects of ventilation: "The continuous and more or less systematic removal of air in a closed space by a properly distributed supply of air in good condition with the object of securing dryness, making up deficiency in oxygen, and removing, or sufficiently diluting, gaseous material derived from occupants and stores, over-heated air, products of combustion and particulate bodies that may be present." The excreta of man himself are, he recognises, the primary exciting causes of diseases. The impurities to be removed are carbonic acid, moisture, smells, and dust, often microbic; for air is fouled by excreta from lungs, mouth, intestine, skin, and by particles rubbed off clothing and bedding, all the conditions on board ship being complicated by dampness off the decks. The de Chaumont standard of ventilation after due consideration is the one adopted by him in a very thoughtful piece of work.

This book is too large and its contents are too various to make it possible to follow the author throughout with criticism or appreciation. We must be content to set down some of his salient points so as to indicate the scope of his industry.

For gun-deafness Elliott's ear-plugs are recommended as more efficient than plasticine, though more apt to be mislaid. The manufacture of distilled water is very clearly described. Mere traces of chlorides are due to priming and of no hygienic importance, but much chloride means leakage of unboiled cold sea water into the distiller (or condenser) tubes, and a great risk, especially in dirty harbours. Drinking water is almost never taken on board United States ships, and as all water is distilled, filters would only be a danger. 7½ gallons of water are asked for per man per day and 15 are wanted in ships with laundries. The need for frequent washing of hands is stated, and it is discussed whether, though a ship is not a hotel, soap and towels might not be provided conveniently for general handwashing, since the cleaner men and ships get to be, the less serious will be the consequences of wounds in action. Trough closets, with seats for 5 per cent. of crew, are prowided with constantly running sea-water. Discharges from the water-closets now often go to an automatic steam sewage discharger which blows them out of the ship. Every drain pipe should have a connexion for steam blow-through and disinfection; chemical disinfectants should not be needed. Sea-bathing should not occur in dirty harbours, nor with temperature of sea below 70° F., nor for more than 20 minutes at any one time. Reliance is placed on sulphur and formaldehyde for gaseous, perchloride of mercury for all other disinfection on ships. Sulphur is used as a culicide against yellow fever (5 pounds per 1000 cubic feet), and

against plague to get rid of rats and with them their fleas. For other diseases formaldehyde is used.

There is a full and lucid account of the principles of dietetics, and mention is made of the complications that had to be met in contriving the varied and popular diet scales of the United States Navy, but the section on meat inspection is too brief to be valuable, and its plates are useless. Alcohol is stated to be a genuine food, but here of less value than sugar, which, besides, produces no subsequent depression. It is further noted that alcohol is popularly no more employed for its food value than is castor-oil; both have some slight food value, but neither is ever used except as a drug. It is pointed out that the expenses and profits of "tenant" canteens come out of the money the men spend on food, chiefly money contributed to them by the State in commutation for rations they do not desire. Hence commutation for all but the higher ranks has been abolished in the United States Navy, which, by the way, issues no ration of alcohol.

The examination and selection of recruits are minutely and usefully discussed. The United States Navy recruits men between the ages of 17 and 35 years, with varying standards, for four years, and if satisfactory and still physically fit they may re-engage within four months of discharge. In 1907-08 17,852 so entered for the first time; of those discharged 57 per cent. (4077) rejoined. The American Service uses the Holmgren test and fingerprints. The author points out that sickness-, invaliding-, and death-rates vary directly and materially with the number of recruits received, and that the morbidity of two navies can hardly be usefully compared unless the proportion of recruits involved is in each case stated. would add that to make such comparisons of value, or comparisons with the health conditions of the male populations of their own country, it is essential that the incidence of diseases should be classified in age groups and the numbers at each age stated, but that is rarely or never done nowadays.

The book is well illustrated, yet wants more diagrams. In preparing a new edition the table of contents should be paged and its headings be printed throughout the book in bold type; 150 pages is too long for the unbroken featureless flow of a chapter. Some misprints are to be corrected. On p. 405, π is not 3 4116. It must be tuneful sometimes on an American ship of war if (p. 468) the potatoes are "pealing." But when we read (p. 154) that "wind taughtens the anchor chains" we gather this is not a misprint, but a different usage, and recall the old yachteman's puzzle, "If all the ropes in a ship are 'taught,' who teaches them?" To sum up, this is a good book, full of facts hitherto unstated or unattainable, and even if at times a little prolix, welcome for its sound and original opinions. It should be in the hands of all naval medical officers and ship surgeons, though its weight-4 pounds-will sometimes bring it to harm in the study hours of an afternoon. We congratulate Dr. Gatewood on his excellent achievement in a too poorly occupied field, and the United States Navy Department and Medical Bureau on their wise encouragement which made it possible thus clearly to state the influences which secure the health of those valuable and costly men, their sailors.

A Test-book of Practical Therapoutics. By HOBART AMORY HARB, M.D., B.Sc., Professor of Therapoutics in the Jefferson Medical College of Philadelphia. Thirteenth edition. With 122 engravings and 4 coloured plates. London: Henry Kimpton. 1909. Pp. 958. Price 21s.

This is an expensive book which has appeared in an English edition 13 times, twice in Chinese, and once in Korean. Although this is not the first time we have reviewed it, its value and its emendations warrant another

full notice. The work is not a handbook of therapentics on the usual lines; it does not give arranged tables and lists of drugs in such a manner that the composition, manufacture, chemical relations, and uses of any article can be found at once. On the other hand, it is not a theoretical work on the physiological action of drugs. Half the volume is devoted to a survey of drugs treated alphabetically. This is not an ideal arrangement, as it destroys the view of the proper chemical relations of the substances under consideration; but it has the advantage of ready reference. It is clear from the adoption of this arrangement and from other points of evidence that Professor Hare intends this work to be useful to those with limited chemical and medical knowledge, who are yet obliged by circumstances to undertake the rôles of physician or surgeon, that is, missionaries, deaconesses, nurses, or apothecaries. To such persons, who would probably also be forced to content themselves with a limited library, this compendium will be very useful. It will be not only useful for everyday references, but forms a broad, balanced, scholarly encyclopædia of medicine written by one who knows his subjects (not subject) and the needs of those for whom he writes.

The next section of the book comprises a hundred pages on remedial measures other than drugs. This section is on the whole very well done, but it attempts too much. Spinal anasthesia is not a safe procedure to adopt when the operator is dependent upon the instructions of a book and the aid of a picture, even if the picture is a beautiful half-page illustration of a gentleman sitting on a stool undergoing the administration. Less risk will be incurred by the student who attempts to apply leeches in accordance with the very bad wash drawing on p. 560. The illustration is quite worthless; no one could apply a leech from looking at it, unless he knew how to apply a leech previously; and no reasonable guide is afforded by the picture as to the proper field of the industries of the leech. Some warning might have been given as to the difficulties of ascertaining which is the "head end" of the leech, and so save the student from the pitfall so graphically described by H. S. Leigh-

"Perchance, reluctant being, I have placed thee wrong side up, And the lips I have been chiding are the furthest from the cup."

Is it any use to try to instruct readers as to the proper method of administering a course of "Weir-Mitchell" rest cure in two pages? Anyone who had to depend upon two pages of a book for their knowledge of a procedure fraught with so many difficult points and responsibilities had better leave it alone for his own credit and the patient's weal. It is not safe advice to say, "Be the symptoms what they may, as long as they are dependent upon nerve strain, this 'cure is to be resorted to, and if properly carried out is often attended with surprising results." If such an important procedure is undertaken in this airy fashion the results will occasionally be surprisingly disappointing to both patient and adviser. But there is no more difficult task in the compilation of books on modern therapeutics than the just estimation of the value of modern methods. In his selection of these methods Professor Hare has shown great judgment.

We would suggest that Professor Hare in a subsequent edition should revise the chapter on feeding the sick. There is no use in the elaborate tables of nutrient values which range from beef or codfish "as purchased" to "beef or codfish" as edible portions, with equivalent statistical estimations of "bluefish" and "shad," "oysters in shell," "cow's milk," "oleomargarine" or "lemons," and a little more attention might have been paid to the recipes for cooking. One recipe for "mulled wine" says: "Boil some spices—cloves, nutmeg, cinnamon, or mace—in a little

water, and add as much of this decoction as is necessary to flavour a wineglassful of sherry or any other wine. If claret is used it will require more sugar than if a less sour wine is employed." We trust we may not encounter "mulled wine" prepared by the inexpert from this recipe. And the author gives us the amount of fats, carbohydrates, and mineral matters in a "red Rhine wine" (which can hardly be procured in England, and still less, we should say, in America).

300 pages are devoted to "Treatment of Disease." This is also arranged alphabetically, and in consequence many of the "diseases" are merely symptoms. This part is carefully written, sound in selection, and not too condensed in style. Many of the illustrations are of moderate value; the coloured plates are of fine quality, but the cost of their production is not justified by their practical worth.

Medical Inspection of Schools. By A. H. HOGARTH. M.B., B.Ch. Oxon., D.P.H., Assistant Medical Officer (Education), London County Council. London: Henry Frowde and Hodder and Stoughton. 1909. Pp. 360, including appendices and index. Price 6s. net.

In this interesting and valuable volume the author gives an exposition of the medical inspection of school children and an account of the methods which are, or which he thinks should be, adopted. The insight gained in his work for the London County Council enables him to describe and to comment on the work in other places, both in this country and abroad, in a useful manner. But, as might be expected from the well-known views of the author, a large part of the book is given over to a discussion of the question whether school medical officers should be independent officers, or whether they should be (or work in conjunction with) officers of the public health service-a question of subsidiary importance from the point of view of many likely to be attracted to the volume by its title. Dr. Hogarth is so strongly persuaded that the school medical officer should be independent, that in perusing the earlier chapters we cannot avoid the impression that both sides of a difficult question are not receiving adequate treatment. On p. 97 there is a table which must have taken considerable trouble to prepare. It gives a list of subjects in relationship with the public health ranging from quarantine to elementary school teachers' superannuation, and of value from many points of view, but in a work purporting by its title to deal with the medical inspection of schools the introductory sentence, which states that the table "illustrates the present condition of medley and chaos," does not do justice either to the performances or the expectations of those who regard school inspection as a legitimate development of the public health service. The sentence immediately succeeding is as follows: "In this incongruous and uncompromising medley school hygiene has to take its place as the newest branch of State medicine." We would suggest that Dr. Hogarth when revising his work for subsequent editions should very materially modify Chapter VIII .. rendering it more instructive and less controversial. "The organisation of a central department of State Medicine" is not essentially a subject to be dealt with in a volume the title of which indicates that it has to do with the medical inspection of schools.

The chapter on administrative routine, though not improved by the effort which is constant through the book to maintain the position that school medical officers should be independent, is of great interest. It contains details of inspection, of registration, of the action taken in connexion with infectious diseases, of special schools, medical certification, annual and other reports, and so forth. The chapter on treatment embodies much valuable matter and would be improved by amplification, and space could easily have been found if topics less germane to the central subject had been

more briefly treated. School clinics and the difficulties connected with their establishment are dealt with in Chapter XV., and the case for their establishment is well stated, as also is the description of the necessary building and furnishing. The cost set forth on pp. 252 and 253 seems heavy and is likely to deter the more parsimoniouslyminded authorities from putting their ratepayers to expense in the matter, but there is not yet sufficient evidence to show exactly what the absolutely necessary amount of expenditure in any given locality should be.

We shall not follow Dr. Hogarth into the more controversial part of his book, but he certainly gives those who desire to do so considerable opportunity. On p. 117, advocating the appointment of medical practitioners as school medical officers, he points out that "a local doctor has a great opportunity of getting into touch with teachers and parents," as it should be part of his duty to "give lectures to the teachers, and arrange conferences at the school for the parents." In this regard Dr. Hogarth attaches little importance to the fact that local practitioners appointed to schools in this manner have an advantage over their fellow practitioners in gaining the good opinion of the people in the locality, and it is probable that at times this advantage might operate unfairly. The question is by which section of the medical profession can the public be best served in the matter of medical inspection of school children, and where should the emoluments of the service be directed. The conditions of urban and rural practice are different, the interests of all members of the medical profession are not identical, and in the consideration of these difficult matters Dr. Hogarth takes a very decided line. We cordially approve of the open way in which he gives views to which he has a perfect right, but it would have been well had he gone more fully into the other side of the question; no general law can, we think, at present be laid down for all the county areas, and good work is being done under both systems.

There is a vast amount of useful information contained in this book and Dr. Hogarth is to be congratulated upon his performance. But those who are looking for a guide to their labours as medical school inspectors ought to know that in his work they will find a good deal of matter which will be of no service to them in their routine, though it may supply them with food for considerable thought upon the whole educational question in connexion with personal hygiene. The book is one which should be read in a critical spirit, as it is important that the reader for some time to come should retain an open mind upon several of the questions upon which Dr. Hogarth makes very decided, and sometimes premature, pronouncements.

The Law Relating to Poisons and Pharmacy. By W. S. GLYN-JONES, Barrister-at-Law. London: Butterworth and Co. Price 10s. 6d. net. 1909. Pp. xxxvi. +410.

THE restrictions with which the legislature has from time to time bound the sale of poisons deserve study by all publicists, whilst the laws which govern the practice of pharmacy, which is an integral part of the art of medicine, should be understood by all medical practitioners. We have, therefore, read Mr. Glyn-Jones's work with the greatest interest, and welcome it as a handy compendium of the statutes, charters, and leading cases dealing with the subjects included in its title.

Free trade in poisons was only abolished in 1851, when in consequence of numerous cases of poisoning the Arsenic Act was passed, restricting and controlling the sale of all colourless poisonous preparations of arsenic, or, as chemists prefer to call it now, arsenium. In the following year the first Pharmacy Act received the Royal Sanction, but

the sale of poisons, providing only for the registration and protection of the title of pharmaceutical chemist. The Pharmacy Act of 1868, however, made it an offence for any person not registered as a pharmaceutical chemist, or chemist and druggist, to sell or keep open shop for the retailing, dispensing, or compounding of certain substances scheduled by the Act as "poisons," and this provision, with some additions made to the schedule from time to time, remained in force in its entirety until April 1st last, on which date the Poisons and Pharmacy Act of 1908 came into operation. Section 2 of this Act provides for the granting by local authorities of licences to persons other than registered chemists, enabling them to sell the poisonous substances referred to in the section for use for specified purposes in connexion with agriculture and horticulture. The reason for this somewhat retrograde enactment was the inconvenience which it was alleged had been suffered by farmers and gardeners owing to the restriction of the sale of poisonous material to registered chemists and druggists in districts where there were no such qualified tradesmen within easy reach.

The Schedule of Poisons has also been recast by the 1908 Act, but is by no means free from ambiguities, and the author of this work has drawn up a list of substances which he considers are comprehended by its terms, and which should at least serve as a guide. He points out, however, that such phrases as "poisonous vegetable alkaloids" involve questions of fact which can only be determined upon the evidence of medical experts. The term "poisonous" being a relative one, the difficulty arises in arriving at the degree of toxicity necessary to bring any particular alkaloid within the schedule. Probably the alkaloids specifically named in the schedule may be taken as a guide, and the expression, "All poisonous vegetable alkaloids not specifically named in the schedule," be taken to mean alkaloids ejusdem generis (as to toxicity) with those specifically named.

With regard to medicines supplied by medical practitioners to their patients which contain scheduled poisons we are reminded that these are only exempt from the provisions of Section 17 of the Pharmacy Act, 1868, if such medicines be labelled distinctly and legibly with the name and address of the seller (i.e., the medical practitioner) and the ingredients thereof be entered with the name of the person to whom it is sold or delivered, in a book to be kept by the seller for that purpose. We cannot recall any case in which this section has been enforced against any medical practitioner not keeping an open shop, nor does the author quote such, but it is hardly satisfactory that it should be so habitually ignored. The book contains an interesting discussion as to the meaning of "acting as an apothecary," and enunciates rules as to when what is known as "counter-prescribing" comes within the meaning of this phrase. Although the author has a somewhat arid legal style we can commend his work to all who are interested in forensic medicine.

LIBRARY TABLE.

Three Voyages of a Naturalist. By M. J. NICOLL. Second edition. Illustrated. London: Witherby and Co. 1909. Pp. 246. Price 7s. 6d. net.—The demand for a second edition of this excellent book of travels within 18 months of its first publication proves that a large number of readers appreciate a well-written account of foreign parts. Mr. M. J. Nicoll was chosen by the Earl of Crawford to accompany him as naturalist on three of the trips in his steam-yacht Valhalla. Lord Crawford states modestly in his introductory note that he took Mr. Nicoll with him that "he might bring back something for the Natural History Department of this in no way restricted the practice of pharmacy or the British Museum." The choice was amply justified, and as the results of Mr. Nicoll's work 500 skins of birds were brought home, of which no less than eight were specimens new to science. The whole book is fresh and delightful to the general reader, and to none more than to those whose lot confines them to cities in the dark, short, and bad days of winter. For it is glorious to read of sunshine and mountains and palm trees, and barrier reefs covered with water so clear that everything is seen as in a glass tank. To the medical reader the book appeals especially in the account of Easter Island and its present and past inhabitants. Cases of elephantiasis were seen in Tutuila Island, one of the Samoan group, where the natives believe that the disease arises from the bites of mosquitoes and say that nearly 25 per cent. of the inhabitants are affected. The stegomyia fasciata was found on Pitcairn Island and also in the Society Islands, but, fortunately, these mosquitoes do not seem to be infected yet with the yellow fever parasite. The three voyages were, one round Africa in the winter of 1902-03; a second to the West Indies in the succeeding winter, visiting the Great and Little Cayman Islands: the third, a voyage round the world in 1905-06. The book is illustrated with 56 plates, four sketch maps, and many text illustrations. It is also provided with a good index.

Air and Health. By RONALD CAMPBELL MACFIE, M A., M.B., C.M. London: Methuen and Co. Pp. 345. Price 7s. 6d. -This unnecessarily bulky volume gives an account of the properties of the atmosphere as they affect health. It is one of a series of books entitled the "New Library of Medicine," which is presumably issued to instruct a non-medical public in various aspects of public health, or in certain conditions of health as they may be controlled or influenced by the State. The volume before us is a plea for fresh air, with which no one can quarrel. There are many besides the members of the medical profession who have to preach the value of fresh air. Some of them have no accurate knowledge of physics or physiology, and have neither the time nor the necessary books to formulate for instructional purposes the slight general impressions which they may have. Such persons are clergymen, schoolmasters and schoolmistresses, nurses, health visitors, mill-owners, superintendents of mines and of indoor labour generally: to these Dr. Macfie's book will prove very useful despite its shortcomings, which no doubt have their origin in the intended scope of his work. The author has had assigned to him the difficult task of translating scientific pronouncements into a language understanded of the people. There are few writers who have this gift, even if they have a sound knowledge of the scientific facts upon which their subject is based. The general information in this volume on the chemistry of air, the physiology of respiration, temperature, and humidity, takes the form of compilations, on the whole not well expressed; they might with advantage be considerably compressed. Some of the problems considered are of a highly complicated nature, such as that of relative humidity, and it is doubtful if a reader of small scientific knowledge would carry away much information from the chapter headed "Humidity and Thermolysis." The latter word is never defined, and is introduced in an entirely haphazard way on page 87. The ignorant beginner would learn far more from a few pages of a well-written, small text-book, such as Balfour Stewart's volume on "Elementary Physics." If Dr. Macfie fails in the arrangement and matter of his introductory chapters it is because, perhaps, he has not been accustomed to elementary teaching on these subjects. When he comes to the practical application of scientific knowledge to ventilation and the evils of foul air he expresses himself well, and avails himself in an interesting manner of the detailed labours of others. The chapters on impure air, trade emanations, dust, and ventilation are excellent and

readable. The remarks on fresh air and the abolition of "colds" are very sound and wholesome. Dr. Macfie's personal experience as superintendent of a large sanatorium for tuberculosis renders his pages on open-air treatment a valuable closing chapter. He gives a picture of the difficulties and opposition which the early pioneers—Bodington (1840) and Henry MacCormac (1855)—encountered, in spite of the courage with which they advocated in vain a system which is now adopted over the whole world. More credit might be given to these two Englishmen, who were really the original priests of the cult of the open window.

Food and Health. By ARTHUR E. POWELL, Lieutenant, Royal Engineers. London: Methuen and Co. 1909. Pp. 266. Price 3s. 6d.—This is an ex-parte exposition of the usual stock arguments in favour of vegetarianism. There is a chapter in which it is sought to condense the teaching of Dr. Haig and others on the degradation products of nitrogenous katabolism. Another chapter consists of "snippets" from all sorts of authors, selected presumably because they support the practice of vegetable feeding. These include such high authorities as "Lieutenant Low in the Food Journal, 1873" (sic), the Panama Star and Herald, and Oliver Goldsmith. The last respectable essayist as an authority on the food of the ancient Britons is funny. In the same chapter is a quotation from Miss Anna Kingsford to the effect that "even the rich people in this province take meat only on fête days." Those who know Brittany, the province mentioned, will know this to be quite incorrect. Lieutenant Powell spoils his own cause, a cause with which we have no quarrel, by attempting to support it by disquisitions on the ethics of killing animals. Then he drags in a chapter on so-called Christian Science and its congeners. Meat. alcohol, tobacco, tea, coffee, and all drugs come under the same ban, and leave the reader wondering at the gallantry of the lieutenant in making so many attacks on such slender equipment.

A History of the Oxford Museum. By H. M. VERNON, D.M. Oxon., and K. D. VERNON. Oxford: At the Clarendon Press. 1909. Price 1s. 6d. net. Pp. 127.—The authors of this little book tell us that its beginnings arose out of the Jubilee celebration of the museum held in the Sheldonian Theatre last year. Nearly all valuable work which has been accomplished in this world derives its value in great part from the struggles and trials which have accompanied its inception and progress, and the Oxford Museum is no exception to this rule. Dr. Vernon and his collaborator trace the study of scientific subjects in Oxford from the modest beginnings of that which is now the Royal Society in 1645 to the present day. From that date until the foundation of the museum in 1855 science, to quote the eloquent words of the Vice-Chancellor at the Jubilee celebration, was in the condition of the cavedwellers among primitive man. "Her teachers, like those of the early Church, wandered about in 'caves and dens of the earth." But the work went steadily forward until "the cockatrice's den," as one worthy don of the old school called the museum, has grown into the present fairly well equipped building. We say fairly well, for there is still plenty of room for more apparatus. It is easy to be wise after the event, but if the fabric of the museum were now in course of erection there is no doubt that the Gothic style would not be the one chosen. We have always thought it a pity that Ruskin and Woodward, thorough artist as the latter was, did not choose a design taken from Tudor or Jacobean architecture. This style with its enormous windows would have given every opportunity for one great desideratum of a museum or laboratory-namely, light, although in the laboratories the characteristic ornamented ceilings would have required modification to avoid the

collection of dust. But as the Gothic style was adopted nothing could have been carried out with more of the feelings of the mediæval craftsman than the decorations by Woodward and O'Shea despite the heavy handicap under which they laboured owing to the vagaries of the Delegates' Council, Convocation, and the contractors. All these difficulties and the way in which they were overcome, more or less, are set forth in Dr. Vernon's interesting little book, a book which we counsel those interested in the progress of science at Oxford to read.

Laboratory Notes on Industrial Water Analysis. By HELEN H. RICHARDS. First edition. New York: John Wiley and Son. London: Chapman and Hall. Pp. 48. Price 2s.-This is a capital manual written for the use of the engineer. The directions are quite sensible, and are embodied in a well-planned series of laboratory exercises. These exercises relate to such practical considerations as the hardness of water, the tendency to form scale, the presence of iron, alkalies, of oxygen dissolved, of any action upon metals, and so forth. The book concludes with a number of tables giving useful data. The author is careful to point out that in a number of cases the questions at issue can only be dealt with by the expert chemist. There remain, however, certain simple cases which the engineer with the clear instruction set before him in this book should be able to decide for himself.

Reports and Analytical Records

THE LANCET LABORATORY.

PYOCYANASE.

(Odol Chemical Works, 59, and 63, Park-street, London, S.E.)

Pyocyanase was referred to in an interesting paper by Dr. Eug. Piasecki on "The Bacteriological Investigations on Some Modern Mouth Disinfectants," published in THE LANCET of Nov. 6th, 1909. Pyocyanase is prepared according to the method of Emmerich and Loew from several weeks old cultures in fluid media of the pyocyaneus organism under special conditions. The liquid is carefully sterilised and keeps for a remarkable time; it is selfpreserving. Pyocyanase, in fact, represents the enzymes derived from the bacillus pyocyaneus, and amongst these ferments is a germicide not only fatal to the bacterium itself, but to many other species. This fact suggested the use of the sterilised culture in internal disinfection. Its germicidal action is certainly remarkable, judging from the bacteriological experiments made with it. Pyocyanase has been employed in a number of diseases, as, for example, diphtheria, scarlet fever, nasal catarrh, diseases of the mouth, and so on. According to Dr. Piasecki, pyocyanase when applied in spray in small repeated doses develops a higher bactericidal action than any other mouth disinfectant which has hitherto been recommended after exact investigation.

ANTI-DIPHTHERIC DRAGÉES.

(THE ANGLO-AMERICAN PHARMACEUTICAL Co., 59, DINGWALL-ROAD, CROYDON.)

These dragées are prepared by the Pasteur Vaccine Co. at the bacteriological institute at Lyons. They present the appearance of a sweetmeat and are allowed to slowly dissolve in the mouth. Each contains, it is stated, 0.25 centigramme of anti-diphtheric serum rich in antitoxic units. The medium is a special preparation which serves to preserve the serum until such time as the dragées are taken. They are intended for use as a preventive of diphtheria and as a guard against throat troubles.

- (1) MASSOLETTES; AND (2) LACTATED IRON TABLETS.
 (ARTHUR H. COX AND CO., LIMITED, BRIGHTON.)
- 1. The massolette is a very ingeniously prepared chocolate-coloured sweetmeat, containing the bacillus of Massol in its highest state of activity. We have carefully examined the preparation in regard to this statement and find that it is true. A single massolette placed in half a pint of milk kept at 100° F. soon developed lactic acid. These bon-bons are designed for what is sometimes called the health milk treatment. 2. The lactated iron tablets undoubtedly afford a satisfactory way of administering iron. The iron occurs along with the lactic acid bacillus.

ANTILEPROL.

(The Bayer Co., Limited, 19, St. Dunstan's Hill, London, E.C.)
Antileprol is described as a specially purified form of chaulmoogra oil, which the Bayer Co. has introduced at the request of Dr. Engel Bey of Cairo, who states that it has the same curative properties as the original chaulmoogra oil (oleum gynocardim), but is much superior to the other, since it enables prolonged treatment to be carried out in most cases without unpleasant complications. The oil is also recommended for tuberculous cases. The sample which we examined was of a light vellowish colour and was contained in capsules of half and one gramme for purposes of administration.

"PACO" DIASTASE MALT EXTRACT.

(PAINE AND Co., LIMITED, ST. NEOTS, HUNTINGDONSHIRE.)

Two specimens of malt extract were submitted to us and both showed a high degree of digestive activity; sample No. 1 proved to digest 10 times its weight of starch at body temperature, and sample 2 as much as 20 times its weight. It is probable that these figures would be doubled under conditions of higher temperature. Apart from their high diastatic activity, the specimens were agreeable to the taste and contained a commendable portion of malt extractives, including proteins, malt sugar, and phosphates. The process of manufacture is evidently carried out with care, preserving as far as possible the initial activity of the diastase in the malt.

TURTLE CUP.

(TURTLE CUP, LIMITED, 15, BURY-STREET, ST. MARY AXE, LONDON, E.C.)

"Turtle cup" affords a convenient and ready way of preparing turtle soup. It consists of a square gelatine tablet which quickly dissolves in hot water. The resulting bouillon is pleasant to the taste and the analysis of it showed the presence of nutritious elements setting aside the question of the value of gelatin. The mineral matter amounted to 10.50 per cent., the moisture to 25.90 per cent., and the total nitrogen to 7.48 per cent. Flavouring materials have evidently been added, but in quantities which do not disguise the much esteemed turtle flavour. "Turtle cup" introduces a very palatable and nutritious soup for domestic use, and it is an advantage to be able to prepare it as required.

USHER WHISKIES.

(FRANK BAILEY AND Co., 50, MARK-LANE, LONDON, B.C.)

The whiskies examined were of a mild type owing to judicious blending. The flavour was delicate and indicated a blend of malt with grain spirit. The estimation of the secondary products endorsed this view. The sample marked "Liqueur" gave on analysis the following results: alcohol by volume, 48.21 per cent.; extractives, 0.14 per cent.; volatile acidity reckoned as acetic acid, 0.022 per cent. The furfural amounted to 1 part per 100,000 parts. The sample marked "Special Reserve" gave the following results: alcohol by volume, 47.67 per cent.; extractives 0.15 per cent.; volatile acidity reckoned as acetic acid, 0.02 per cent.; and fixed acidity reckoned as acetic acid, nil. The

former specimen showed greater age. Both whiskies were clean to the palate and free from coarse flavour.

BIPSINE BREAD AND BISCUITS.

(Bipsine Food Co., Westminster Estates, Limited, 17, Waterloo-place, London, S.W.)

It is stated in regard to Bipsine bread that its digestibility is enhanced by adding to it a small quantity of pepsine. However that may be, our analysis gave the following results: moisture, 35.70 per cent.; total protein, 5.73 per cent.; mineral matter, 1.50 per cent.; and soluble matters (cold water), 12.00 per cent. These results do not differ materially from those obtained with ordinary well-made bread. The texture of the bread was uniform and the flavour good and appetising. Further, the loaf keeps well and develops no acidity. We strongly approve the method of delivering Bipsine bread to the consumer, each loaf being wrapped in white paper with a band outside which serves as a guarantee label. Bipsine biscuits are made on similar lines and the result is satisfactory. They are well baked and crisp and possess an attractive flavour.

THE JOHN HERBERT WELLS FUND.

THE following is the fourth list of subscriptions to the John Herbert Wells Fund. Further contributions will be gratefully received by the Earl of Dalhousie and Mr. Julian G. Lousada, honorary secretaries and treasurers of the fund, at 16, Old Broad-street, E.C., or by ourselves at this

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, NOV. 24TH.

THE Council resumed its sittings. Sir DONALD MACALISTER, the President, was again in the chair.

The Medical Curriculum.

The sitting was mainly occupied with the consideration of penal cases. However, an interval of time intervening between two cases was utilised for continuing the debate on Dr. J. Y. Mackay's motion expressing approval of the following recommendation of the Education Committee:

"That the following be added to the Recommendations of the

"That the following be added to the Recommendations of the Council in regard to Professional Education.

"For the purposes of this Recommendation the subjects of the curriculum are arranged in two groups, the Earlier Group comprising the Preliminary Sciences and Anatomy and Physiology, the Later Group embracing all the remaining subjects, exclusive of Pharmacy

Pharmacy.

"The Regulations of the Bodies should be so framed as to secure (1) for the study of the subjects of the Later Group the reservation of a period equivalent in value to 2; academic years (27 months) of undivided study, half-time value being allowed for periods of work in which studies in the Earlier and Later Groups overlap; and (2) the reservation of a period of two academic years (21 months), in which studies of the Later Group shall have the undivided attention of the Studies."

Dr. NORMAN WALKER (resuming the debate) said that he had long been interested in medical education, but it was only in the last 18 months that he had been a member of the committee in Edinburgh which had been considering the question of the curriculum. He had learned how easy it was to criticise the medical curriculum, but how difficult it was to fit in the different parts one with another. He recognised that the earlier subjects, if properly taught, were of immense value in the medical curriculum. The Council did not count botany and zoology amongst these. All it required was an elementary course in biology. No one could deny that it was an admirable introduction to anatomy. The amount of apparatus used in practical physiology made it important that students should have more acquaintance with physics than school teaching could afford. Chemistry could be taught in such a manner as to be perfectly useless to a medical student, or it might be taught so as to be an admirable introduction to physiology and pharmacology later. All depended on how subjects were taught. The object of the motion, he understood, was to try to make it more certain that the clinical subjects should get fuller consideration. The importance of the earlier scientific training could not be exaggerated. He agreed with the remarks of Sir Thomas Fraser that it was very important that a thorough groundwork should be laid in the case of every student. That was not all. The State required that the Council should only admit to the Medical Register those persons who had a practical knowledge of medicine, surgery, and midwifery. He might take it upon himself to speak for the younger generation of Edinburgh teachers when he said that they recognised the importance of clinical teaching. In a report they had recommended that during the last three years of the curriculum the hours between ten and half past one should be spent in the wards of the hospital. Of course, in connexion with a motion such as the Council was now discussing, there were details which were matters for individual medical schools, such as classes, teachers, buildings, and domestic discipline. What the Council was concerned with was rather that the final subjects should be adequately taught. If the recommendation were passed, the licensing bodies which did not at present accede to the 21 months of undivided final study would find it easier to insist upon this in the future. He hoped that the recommendations of the Education Committee would be passed as an instalment of what required to be done in medical education.

Dr. FINLAY thought that there was a good deal of complexity introduced into the proposal of the Education Committee by the mention of "overlapping" in it. That would give rise to a great deal of confusion in the minds of the students. If the question of overlapping could be got rid of it would be a great advantage both to students and teachers. A finished medical man could not be turned out

in five years or in ten years, but a good foundation could be given him in his student years for his clinical work. He did not propose to vote against the motion.

Sir CLIFFORD ALLBUTT said that certain universities were only partially responsible for the clinical teaching of their students. He might remark at the outset that the debate so far as it had proceeded had not left a very definite impression on him. It appeared to him that the speakers had been mixing up different things. They had spoken about universities and the great professional corporations, and mixed up their standards with what was the duty of the Council. The duty of the Council was to fix an irreducible minimum of medical education with which a man should be allowed to go into practice. The Council had not to consider the com-Plete training of students from the ideal point of view. What it had to consider was a case where a father who had not a very large income desired his son to follow him, say, in a suburban practice bringing £500 or £600 a year. It was a grave statement to make that a man could not be well educated in five years as a competent resourceful family practitioner in a modest sphere. If he could not be so educated in five years then medical teaching must be very much at fault. The first year of study had been referred to. If more was to be expected from the medical student than a certain adequate foundation of the rudiments of chemistry, biology, and physics, then too much was being asked. He thought that the rudiments of these subjects should be given in the schools. At Cambridge steps had been taken in this direction. If the student was set to work on his anatomy to begin with, along with some advanced chemistry, he could in the second year take anatomy and physiology. Then he could have three years in which pathological work would go on concurrently with medicine and surgery.

The PRESIDENT remarked that he wanted the Council to have a clear idea of what was proposed by the Educa-tion Committee. There had been a large number of tion Committee. speeches dealing with various stages of the curriculum, but the debate really centred on one point—what was to be done to safeguard the second part of the curriculum. The proposal was that the Council should represent to the licensing bodies that their regulations should be so framed that the study of the final subjects, including such subjects as pathologv, medicine, and surgery, should extend over two and a half years, and in any case that the instruction in them should extend over two years after anatomy and physiology had been completed. If the Council for the first time made that announcement, it would have taken a definite step in indicating to the licensing bodies the importance which it attached to the final subjects. Sir Clifford Allbutt had pointed out the fact that the Council was not legislating for an ideal curriculum which would extend over seven or eight years, but for a minimum curriculum by which a guarantee was given to the public that a medical man was a safe practitioner. Members of the Council need only take into account what in the minimum curriculum of five years should be the minimum of time and study devoted to the practical subjects. If they passed the recommendations of the Education Committee they would still allow the various bodies to adjust the time for the preliminary sciences as they might see fit. This would allow them to make the experiments which the University of Cambridge was doing in respect to these subjects. He did not think that it was desirable that there should be absolute However, he thought that the uniformity as to that. Council should at least say that in every case the last two and a half years of the medical curriculum should be occupied with the final subjects and two clear years should be given to nothing else. If the Council took that line it would be making a definite advance. He could not help thinking that overlapping was a difficulty, and that it was in the interests of the medical bodies that the recommendations of the Council should be framed in as simple terms as possible.

Dr. J. Y. MACKAY remarked that he proposed to substitute a motion in which the word "overlapping" did not occur.

The debate was again adjourned.

Penal Cases.

The Council considered penal cases for the greater part of the sitting.

The first was the consideration (adjourned from May 28th, 1909) of the facts proved against Mr. William John Watson.

The Dental Committee submitted a report in which it was stated that—

William John Watson has since the date of the last hearing of this case observed his undertaking to discontinue all advertising and to have no connexion with unqualified practitioners and no objection has been taken to the mode in which his profession has been carried on. The said William John Watson further undertakes not to advertise in future or to have any connexions direct or indirect with unqualified practitioners.

After deliberation in private,

The PRESIDENT said: I have now to say that the Council does not see fit to erase from the Dentists Register the name of William John Watson.

The next business was the consideration (adjourned from May 28th, 1909) of the facts proved against Charles Morgan in regard to whom the Dental Committee, at its meeting on Monday, Nov. 22nd, 1909, drew up a supplementary report. In that report it is stated that—

The committee find upon the evidence that Charles Morgan has since the date of the last hearing of this case observed his undertaking to discontinue all advertising and he further undertakes not to advertise in future.

The PRESIDENT, in delivering the decision of the Council, said: I have to announce that the Council does not see fit to direct the Registrar to erase from the Dentists Register the name of Charles Morgan.

The Council then took up the consideration (adjourned from May 28th, 1909) of the facts proved in the case of Thomas Torrens McKendry, registered as of 39, Wellwoodroad, Goodmayes, Ilford, Essex, M.B., Bac. Surg., 1894, R. Univ. Irel., who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you have knowingly and wilfully on various occasions, and in particular on the 20th day of February, 1909, assisted one E. C. Dalby, a person not registered as a dentist, in carrying on practice as a dentist by administering anæsthetics on his behalf to persons coming to him for treatment, and that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainant was Dr. Victor Albert Chatelain.

At the close of the proceedings on Wednesday, May 28th, 1909, the PRESIDENT, addressing Dr. McKendry, said: "Mr. McKendry: The Council has postponed judgment till the November session, when you will be required to attend in person and to produce evidence, more particularly from medical colleagues in your neighbourhood, as to your professional good conduct generally in the interval, and in particular that you have not repeated the offence of which complaint has been made."

Dr. McKendry again attended.

Dr CHATELAIN, the complainant, was not present, but a letter was read from him in which he stated that he had no further evidence to produce against Dr. McKendry.

Dr. McKendry gave evidence on his own behalf. He put in three testimonials as to character from medical practitioners—viz., from Mr. A. J. Pattison and Mr. H. W. Garden of Goodmayes, and Dr. T. R. Atkinson of Chadwell Heath. He gave an undertaking not to administer anæsthetics for unregistered persons in future.

After deliberation in camera,

The PRESIDENT said: Mr. McKendry, the Council have taken note of the evidence you have produced and of your undertaking, and they have come to the decision that they do not see fit to direct the Registrar to erase you name from the Medical Register.

The Council then considered the case of Robert Wiseman Cunningham, registered as of King's Island, Tasmania, M.B., Mast. Surg. 1895, M.D. 1904, Univ. Edin., who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you abused your position as a medical man by committing adultery and eloping with Alice Mary Wigram, whose husband you had been attending professionally and while you were the medical attendant of the family, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated June 11, 1909, in the case of Wigram v. Wigram and Cunningham, in which you were the co-respondent, and that in relation thereto you have been guilty of infamous conduct in a professional respect.

Dr. Cunningham did not attend, nor was he represented. A letter was read from him in which he dealt with the matters referred to in the charge.

The Council briefly deliberated on the case in camera.

The PRESIDENT said: I have to announce that the Council have judged Robert Wiseman Cunningham to have been

guilty of infamous conduct in a professional respect and have directed the Registrar to erase from the Medical Register the name of Robert Wiseman Cunningham.

The Council then considered the case of Alexander Riddle Stower, registered as of 80, Shaftesbury-avenue, London,

W., "in practice before July 22, 1878."

The Dental Committee in their report on this case stated that the complainants were the British Dental Association. The committee further found that-

The said Alexander Riddle Stower was registered in the Dentists Register on July 19, 1879, as "in practice before July 22, 1878," and his address in the Register for the current year is 80, Shaftesbury-

and his address in the Register for the current year is 80, Shaftesburyavenue, London, W.

The said Alexander Riddle Stower has advertised his professional practice: (a) By advertisements carried by two sandwich men parading Oxford-street; (b) by the issue and circulation of leaflets and a calendar adorned with a female portrait; and (c) by advertisements in the public newspapers describing himself as "Stower's Dental Association," and asking for agents; (d) by various conspicuous notices on the front of 80, Shaftesbury avenue, where he carries on his profession, consisting of notices in six windows, a swinging sign at the entrance, a show-case illuminated with electric lights, and other notices both outside and inside the premises. These advertisements and leaflets are of a highly objectionable character. The said Alexander Riddle Stower stated that some of the advertisements complained of had been withdrawn, and that it was not his intention to employ sandwich men or to advertise in the newspapers in future.

Mr. Stowers who estanded personnelly before the Conneil.

Mr. Stower, who attended personally before the Council, was represented by Mr. E. H. Cannot. The British Dental Association was represented by Mr. Hart.

Mr. CANNOT addressed the Council on behalf of Mr. Stower, who, said counsel, regretted very much that he had by advertising overstepped the bounds of professional pro-priety. With regard to the advertisements by sandwich-board and in the newspapers, Mr. Stower felt that those were improper, and he discontinued them before complaints were made, and he would not again put them into use. With reference to the notices in front of his premises, Mr. Stower desired to have the kind consideration of the Council. He practised in a neighbourhood where he appealed to a particular class of patients and where there were a great many unregistered persons who in carrying on their profession made great displays of notices. If he were prevented from making the same display to let the people in the neighbourhood know he was carrying on the profession of dentist he would be crushed out of existence. He thought that matter was worthy the consideration of the Council.

Mr. HART, on behalf of the British Dental Association, said the Council had received only a limited assurance that a cessation of the advertisements which the committee found objectionable would take place. No assurance had been given that the issue of the leaflets and calendars - to take two marked instances—would cease. He did not think that professional etiquette was in a state of flux and varied with the neighbourhood in which a practitioner found himself. It was not open to Mr. Stower to come to the Council to ask for a hall-mark for the advertisements on his premises on the ground that he claimed to compete with unregistered men on the same lines that they adopted.

The Council then deliberated in private.

When the public were readmitted the PRESIDENT said: Alexander Riddle Stower, I have to inform you that on the facts proved in the report of the Dental Committee it has been held that you have been guilty of infamous or disgraceful conduct in a professional respect and that the Registrar has been directed to erase from the Dentists Register the name of Alexander Riddle Stower.

The Council then adjourned.

THURSDAY, Nov. 25th.

The Council resumed its sittings. Sir DONALD MACALISTER, the President, again occupied the chair.

Penal Cases.

The Council continued the hearing of penal cases.

The first considered was that of Frederick Morrish Pierce, registered as Mem. R. Coll. Surg. Eng. 1867, Lic. Soc. Apoth. Lond. 1867, Lic. R. Coll. Phys. Lond. 1868, M.D. Q. Univ. Irel. 1868, now of 50, Gordon-square, W.C., who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:

That, being a certifying surgeon appointed by the Secretary of State under the Factory and Workshop Act, 1901, you, for the purpose of evading the conditions under which you were appointed, which required the personal fulfilment of the duties prescribed by the Act (except under the circumstances and on the conditions laid down in the instructions issued by the Secretary of State), knowingly and wilfully employed another registered medical practitioner (viz., Edward Arthur

Burgess) to perform your duties; and that in order to carry out this system of evasion you committed the following offences, viz.:—

"(a) It being your duty as such certificates of fitness for employment in factories and workshops, and to grant certificates in suitable cases, you allowed the said Edward Arthur Burgess to conduct the examination for you and to sign your name to certificates that you had personally examined certain persons on certain dates named, and that they were fit to perform the work on which they were engaged.

"(b) It being your duty as such certifying surgeon to investigate and report upon certain accidents, you allowed the said Edward Arthur Burgess to visit the works and the injured persons for you, and you thereafter signed certificates that you had personally investigated the causes of such accidents and had personally investigated the causes of such accidents and had personally taken the evidence of such injured persons when in fact you had made no such personal investigation and had not personally taken such evidence, but the certificates were subsequently filled up by you upon information furnished to you by the said Edward Arthur Burgess.

"(c) It being your duty as such certifying surgeon personally to examine and certify persons employed in certain dangerous processes, you allowed the said Edward Arthur Burgess to examine such persons on your behalf and to insert the necessary particulars in the Health Register, which you afterwards signed and in other cases you signed the said Register in advance, the necessary particulars being afterwards filled in by the said Edward Arthur Burgess when he visited on your behalf.

"And that in relation thereto you have been guilty of infamous con-

And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The original information on which this charge was based was laid before the Council by the Home Office

Dr. Pierce was unable to attend personally owing to

illness, but he was represented by Mr. Griffithes, solicitor. Mr. WINTERBOTHAM, the Council's solicitor, said it was not a mere question here of a breach of regulations. charge was a systematic conspiracy on the part of Dr. Pierce to mislead the factory inspector by doing what he knew was not permitted. It was a serious matter for the public, for whose protection these medical men were appointed. Dr. Pierce had charge of a district in Manchester. There was one factory in the district where dangerous trades were carried on. There was a health register which had to be signed by the medical man on the occasion of each of his visits. But in this register the number of Dr. Pierce's signatures did not correspond with the number of visits, and it was perfectly obvious they had been signed in advance because there were fewer visits than signatures. When Mr. Burgess was the duly appointed deputy of Dr. Pierce the former signed his own name in the usual and proper way. But Mr. Burgess paid visits for Dr. Pierce when he was not the authorised deputy, and the register showed three visits which were paid by Mr. Burgess where the particulars were filled in in his (Mr. Burgess's) handwriting and signed by Dr. Pierce in his own writing. Either before or after these visits Dr. Pierce must have written his signature. Other registers, said the solicitor, showed similar irregularities. With regard to the first charge the solicitor read certificates granted for the employment of young persons under 16 in factories, and declared that although they purported to be signed by Dr. Pierce the examination was made by Mr. Burgess, who signed Dr. Pierce's name. As to charge (b) the solicitor produced documents relating to several accidents in factories. At this time Dr. Pierce was living in London. Mr. Burgess visited the works and the injured persons and supplied the particulars to Dr. Pierce, who wrote them out the necessary papers in London and sent them, or at least some of them, to be posted in Manchester. The statement to which Dr. Pierce adhered his signature was this: "The cause of the accident was personally investigated by me at the works and the evidence of the injured person was personally taken by me." That was not correct, and the injured men if they had been called upon to produce the doctor's certificate in court in prosecuting a claim against their employers might have been placed in a serious position. The solicitor read some correspondence which took place between Dr. Pierce and Mr. Burgess, which he said showed that Dr. Pierce understood the gravity of the offence he was committing.

Dr. B. ARTHUR WHITELEGGE, chief inspector of factories, gave evidence as to the duties of certifying surgeons, and said that Dr. Pierce, who had been a certifying surgeon for 38 years, had now resigned. Up to the time these complaints were made Dr. Pierce had discharged his duties efficiently.

Mr. J. E. ASHWORTH, inspector of factories in charge of the Manchester district, also gave evidence, and, in answer to Mr. Griffithes, he said he did not regard Dr. Pierce's district as an exceptionally heavy one. It was about the average.

Do you find the registers, as a rule, are kept neatly?—

As a rule; if there are any irregularities we draw the doctor's attention to them.

Mr. Bodkin: The neatness of the registers would depend on the handwriting of the particular doctor.

WITNESS: Yes. We all know how doctors write.

Mr. E. A. BURGESS then gave evidence as to the various

allegations made in the charge. Mr. GRIFFITHES addressed the Council on behalf of Dr. Pierce. He read a declaration from his client in which it was stated that Dr. Pierce in 1872 was appointed to the position of certifying surgeon for South Manchester. Up to 1909 he held that post, and then resigned it on account of illhealth. During the whole of this period of service there never was any complaint against him until the one which had been brought forward to-day. He had inspected about 50 factories on an average in the week, and examined about 100 persons. It was necessary to do this work on five days of the week in order to meet the convenience of employers and employed. For several years he had suffered from gout. These attacks made him unable to discharge his duties as certifying surgeon. It was upon these occasions that he made arrangements with Mr. Burgess, and Mr. Burgess had been accepted as his substitute on former occasions. He was a thoroughly competent man, and in his (Dr. Pierce's) opinion it was a lesser evil to allow him to perform these duties than to cause great delays and inconvenience to employers and employed. Owing to deafness and the broken condition of his health he was unable to be present before the Council. He expressed his sincere regret as to the breaches of the regulations which had occurred. He appreciated the extent of his error for doing so, and he ought not to have allowed himself in his anxiety for the employers and employed to depart from the regulations. Mr. Griffithes said that these facts had been made in a statement that morning. He would be wanting in his duty if he attempted to say that Dr. Pierce was not doing wrong. There was a breach of the regulations of the Home Office which amounted to an irregularity, but it might perfectly well have been dealt with by the Home Office itself. He hoped to satisfy the Council that it was not a case for the exercise of their powers under the Act, and that his client had done nothing which would come within the description of infamous conduct. He went on to point out that Dr. Pierce had been living as much in Manchester as in London. He had rooms in Manchester where he received young persons for certificates and he had lodging where he resided. Surely as certifying surgeon he was at liberty to reside where he liked, provided he gave sufficient time to his duties and discharged them properly. Dr. Pierce had for 40 years been a member of the medical profession. He had broken the rule that he must personally discharge those duties. No doubt he had endeavoured to conceal this. It was only human to do so. The rule said that no standing deputy could be appointed without official sanction. At the same time the rule was not a reasonable one. It was obvious that serious inconvenience might be felt. There were duties to be performed by the certifying surgeon promptly almost every day. If the certifying surgeon were suddenly taken ill, and if the superintending inspector from whom he was to get the authorisation for the appointment of a deputy was not at hand, there might be a serious delay. He came now to what he regarded as the most important remark he had to make in Dr. Pierce's The man whom he employed for his duties was a favour. duly qualified medical man, who had before been authorised over and over again by the inspectors. There had been no delegation of duty to an unfit person. Mr. Burgess had assisted Dr. Pierce generally with the authorisa-tion of the factory inspector on previous occasions. No human being had been injured by the breach of the regula-The Home Office had got their returns. It was admitted that the passing of a mere piece of paper would have rendered regular what had been done irregularly. Could the Council, therefore, say that Dr. Pierce had been guilty of anything more than a breach of duty which might be forgiven to him? He asked the Council to believe that Mr. Burgess was exaggerating the extent of the unauthorised work which he did every day for Dr. Pierce.

Mr. WINTERBOTHAM briefly replied and laid emphasis on the fact that the correspondence of a private nature submitted to the Council showed that what had been done had been done deliberately by Dr. Pierce,

After deliberating in private,

The PRESIDENT, in announcing the decision of the Council, said: Mr. Griffithes, I have to inform you that the Council have judged Frederick Morrish Pierce to have been guilty of infamous conduct in a professional respect and have directed the Registrar to erase from the Medical Register the name of Frederick Morrish Pierce.

The next case was that of Robert Orr, registered as of Ceres, Fifeshire, M.B., Bac. Surg. 1901, Univ. Glasg., who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor :-

That you were on October 1, 1907, convicted at the Sheriff Court of Fife at Cupar of the following offence—namely, of assaulting a constable of the Fifeshire Constabulary while engaged in the execution of his duty. And that you were on July 6, 1909, convicted of the following offence—namely, of breach of the peace and of assaulting James Arthur, Helen White or Arthur, Catherine Dempsey or Kerr, and Catherine Ouis. Catherine Quin.

Dr. ORR appeared in person but was not represented by counsel. He made a statement on his own behalf and said that in the case of the first conviction he had had extreme provocation. On the second occasion he had tried to intervene between some persons, and unfortunately he got the worst of it. He regretted that he had to appear before the Council.

The PRESIDENT: Were you sober on those occasions ?

Dr. ORR: Yes, sir, in both cases.

After deliberating in camera,

The PRESIDENT said: Mr. Orr, the Council have given careful consideration to the question of your convictions and the circumstances connected therewith, and have decided to postpone judgment thereon till the May session, when you will be required to be present, and it will be in your interest to produce on that occasion testimony of a satisfactory character from persons of position in the neighbourhood in which you live as to your conduct and character in the interval.

The Council then adjourned until Friday, Nov. 26th.

Brighton DISPENSARY CENTENARY. — The Brighton, Hove, and Preston Dispensary celebrated its centenary on Saturday last. The need of such an institution for the benefit of the poor of the town first impressed itself upon one Richard Phillips, a Quaker, and with the assistance of Dr. Tierney, afterwards Sir Matthew Tierney, physician extraordinary to the Prince of Wales, who afterwards became head of the medical staff, a meeting was called on Nov. 27th, 1809, which was presided over by the Earl of Chichester. At this meeting the following resolution was carried:-

That notwithstanding the liberal aid which medical gentlemen have extended to the poor, the establishment of an institution for administering to them advice and medicine gratis and for promoting vaccination would be attended with extensive advantage.

The first name of the institution was "The Brighthelmston Dispensary and Sussex General Infirmary" and for some years it had quite a nomadic existence. In 1847 the present building in Queen's road was erected, and at the jubilee of the institution a branch was formed at Hove, and a Samaritan Fund was opened to enable medical officers to order nourishment for patients. In 1884 the dispensary still further increased its scope of usefulness by opening a branch in the north part of Brighton and thus the institution became what it now is, the Brighton, Hove, and Preston Then the Hove or western branch had Dispensary. to be removed, having outgrown its original quarters, and larger and more up-to-date premises were erected at a cost of £6000. Some little difficulty was experienced in raising this sum, but the debt is now cleared off with the exception of sums involved by new works at the Hove branch in connexion with the centenary. These have been carried out at a cost of £2400, and the premises were opened on Nov. 27th in commemoration of the jubilee of the inception of the western branch and the centenary of the parent institution. A considerable sum still remains to liquidate this debt of £2400; while also an appeal is being made, again in celebration of the centenary, to increase the endowment of the Samaritan Fund, the amount of which has remained the same for nearly 50 years, during which period the population of the borough has increased from 70,000 to over 150,000. In connexion with this fund a sum of £2500 is being asked for. About £400 have already been collected.

THE LANCET.

LONDON: SATURDAY, DECEMBER 4, 1909.

The Housing and Town Planning

When the House of Lords dealt a second time with this very tar-reaching measure, which is of such vital importance to the health and comfort of so large a portion of the community, the Peers had no grounds for complaining of the spirit in which their numerous amendments had been considered in the House of Commons. The attitude of Mr. Burns was entirely conciliatory. Although he is not a man to regard half a loaf as better than no bread he was evidently anxious to see this useful measure, upon which he has expended such an infinite amount of trouble, inscribed upon the Statutebook, although the Lords had already deprived the Bill of not a little of its public utility.

Of the 181 amendments introduced by the Lords it was considered by the Government that not more than four or five were destructive of the principles and character of the Bill, and Mr. Burns, on reviewing the whole position, thought the Bill ought to pass. principle underlying many of the Lords' objections practically amounted to distrust of the Local Government Board as an entirely unprejudiced and final tribunal in connexion with the compulsory purchase of tand. It is difficult to obtain anything approaching perfection in most mundane affairs, but it seems to us that the least undesirable method of acquiring the land is that proposed by the Bill. It must not be forgotten that the lengthy and expensive method provided in previous Acts has been one of the reasons of the failure of such measures to bring about the objects for which they were passed, and if the hoped-for good results which are anticipated from the Housing Bill are to be realised simpler methods must be introduced. It cannot be denied that some of the procedures proposed in the Bill savour somewhat of bureaucracy, but, on the other hand, no responsible person has, so far as we are aware, brought any charges of bureaucratic methods against the Local Government Board in connexion with any of the multitudinous duties which devolve upon the officers of that department. What are known as provisional order methods are apt to lead to hesitancy in action and to the failure of the statutes which embody them as part of their machinery. As Sir Walter Foster. an old Parliamentary Secretary of the Local Government Board, explained, the proposal that an order for the acquisition of land should be laid on the table of both Houses of Parliament was "a subtle method of delay," and we are afraid that several of the amendments introduced by the Lords have about them a suspicion of intentional lives.

Another important amendment of the procrastination. Lords was that which proposed to allow the landlord an appeal to the local county court against a notice requiring him to execute certain works, but this Mr. BURNS would not accept, although he eventually agreed to a compromise to prevent a deadlock. But perhaps the strongest position which the President took up in relation to any point of the Bill was in reference to the clause, which has the effect of putting an end to further erection of back-to-back houses, but which permits the erection of tenements placed back-toback if the local medical officer of health certifies that the several tenements are so constructed and arranged as to secure effective ventilation of all habitable rooms in every tenement, a proviso which has apparently been introduced to get over the difficulty presented by blocks of model dwellings. The Lords endeavoured to obtain the same condition as regards back-to-back houses subject to certificate as to ventilation by the local medical officer of health, but, despite the representations from Leeds, where there is a local Act enabling back-to-back houses to be erected. and where the city council have expended over a million sterling in substituting good for bad back-to-back houses, Mr. Burns asked the House to reject the Lords' amendment. All fair-minded persons must feel a certain amount of sympathy with Leeds, but, nevertheless, the strong action of the Government will meet with the support of nearly all

In Part III. of the Bill the Commons had introduced a clause giving to the Local Government Board power to prescribe the general duties of the county medical officer of health, and also providing that these officers shall have a right to appeal to the Local Government Board against dismissal. We think that Mr. Burns was right to insist upon the retention of this clause. It was urged by speakers in both Houses that this provision was not necessary, but everyone really familiar with the work, either practically or through their annual reports, of county medical officers of health must feel that a provision of this nature will enormously strengthen the hands of these officers, who will now be brought, as Sir Walter Foster observed, into intimate relations with property owners. Having regard to the multitudinous interests affected by the Bill everyone anxious for better housing must have welcomed the fact that when the amendments of the Commons were finally dealt with in the Upper House the Lords evinced a conciliatory spirit and that, with one exception, practically all the points upon which the Commons had insisted were allowed to remain as they were, while as regards the outstanding difficulty with reference to the compulsory acquisition of land a compromise has, we are glad to see, been arrived at, and thus the controversy between the two Houses has been ended and the Bill awaits the Royal consent.

We cordially congratulate Mr. Burns upon his eminently statesmanlike conduct of this measure through the House of Commons, and although, as we have said, the Bill has been shorn of some of its strength it still contains provisions of the highest possible value which, if vigorously applied, should largely transform the conditions under which a large section of the relatively poor at present spend their lives.

Spinal Anæsthesia.

THE position which spinal anæsthesia is destined to hold in the field of surgery in the future is not yet clearly to be discerned. Its true claims, indeed, at the present day are not very easy to state with precision, for it is a comparatively new venture and its methods are not yet certain, nor are the opinions as to its value amongst those who are practising it by any means unanimous. The latest development of the method, one for which its author claims the attainment of absolute safety, has recently been shown in London, and this demonstration makes timely a few remarks upon the general question of anæsthesia without loss of consciousness, and upon M. Jonnesco's method in particular. This method, as many of our readers are aware, has for its distinguishing feature the addition to the analgesic drug of a certain proportion of strychnine. The neutral sulphate of strychnine is employed and it is added in amounts which vary from + milligramme to 1 milligramme. This is used with a quantity of stovaine varying from 1 up to 10 centigrammes, and the amount of liquid injected never exceeds 1 cubic centimetre at a time. The smaller quantities are used in young or feeble subjects and in the high injections, the larger quantities in adults and in the lower injections. The high injections are made between the first and second dorsal, the lower between the twelfth dorsal and the first lumbar spines. No care is taken to keep the patient's head raised above the level of his spine, if for the operation any such position as the Trendelenburg is desired; indeed, when an anæsthesia of the face, or skull, or neck is desired M. JONNESCO places the patient almost directly after the injection in a horizontal or head-down position. It will be seen, then, that the fears which have been hitherto held of this position, fears based upon an apprehension that the bulbar centres might be paralysed, are put aside as groundless, and that they are so M. JONNESCO claims to be the result of the addition of strychnine. He believes that this acts more quickly than the stovaine and stimulates the bulb so effectually that the subsequent paralysing action of the stovaine is unable to do harm. It is obviously too early to talk of absolute safety in connexion with a procedure that has stood the test of only about a hundred and twenty cases. But there is at least evidence to show that a proceeding, which was hitherto thought to be attended with certain danger, can at any rate be accomplished without disaster. In all matters of anæsthesia it is essential to insist upon a high standard of safety, and experience in the past has shown how great may be the expenditure of life involved by the too hasty adoption of a new method or drug as being absolutely safe. We need only refer to the wide and haphazard way in which ethyl chloride was at first used, and the many fatalities that occurred before the potency of and the proper way to employ the drug were finally recognised, to make clear how necessary it is that every development in anæsthetics should be approached with care and rigidly tested.

Spinal anæsthesia does not appear to be welcomed so warmly in Great Britain as in some of the continental countries, and we believe that the main reason is that there is less cause to be dissatisfied with the use of general

anæsthetics here than there is abroad. We talk a good deal of our defaults in the matter, but we appear to be ahead of many of our neighbours. Whether it is because in these islands chloroform was first used and nitrous oxide discovered, while ether, introduced by a man of the English-speaking race, was given a ready acceptance whether it is this inheritance or for some other reason, the fact remains that in Great Britain we have a number of medical men devoting their professional efforts entirely, or almost entirely, to the study and practice of anæsthesia. This is not the case on the continent, where the administration of anæsthetics is more often left in the hands of the comparatively inexperienced, while the operating surgeon is held responsible for the results. The requirements of modern surgery make such a condition of affairs very dangerous, and this appears to be felt in Roumania, for M. JONNESCO has alluded to the anæsthetist as a person "often inexperienced and never responsible." This being the case we can well understand the eagerness with which surgeons in Roumania have welcomed a method of producing anæsthesia that they can take into their own hands. And the Roumanian surgeons seem to have a more docile material to deal with than the British patient is likely to be, and just as in other affairs of life morals have been said to be merely a "matter of geography," so there may be a racial side to the administration of anæsthetics. We were awakened to this point of view by the very striking slides illustrating M. Jonnesco's lecture before the Royal Society of Medicine. that appeared usual and unobjectionable to the patient in Bukharest would be regarded as intolerable by the average hospital patient here. Now may there not be something of the same difference between Roumanian operators and anæsthetists and British operators and anæsthetists in our estimation of the absence or presence of pain? May it not be that the patient under spinal anæsthesia with occasional evidences of discomfort, if not of actual pain, would make the British surgeon uncomfortable and dissatisfied in a manner that does not so easily happen to his confrères abroad? The same racial differences affect the patient too, and we suspect that an amount of mental anxiety and distress may be experienced by the conscious patient which would be strongly objected to by our own countrymen and women, even if they felt no physical pain. M. JONNESCO claimed it as one of the great advantages of his method that consciousness is not abolished. There are, however, certainly many persons who would prefer to know nothing of what is going on whilst they are undergoing an operation, even though there are, no doubt, some who dread losing consciousness.

There are some fields of practice in which the value of spinal anæsthesia would be, it appears to us, immense. In naval and military work, for instance, the simplicity and portability of the apparatus required and the possibility of being able both to anæsthetise the patient and to operate single-handed would be of great advantage. Similarly, for emergency operations in country districts to be able to employ this method would often be of the highest service. Moreover, if its claims to be as safe as general anæsthesia in good hands should be established, there will doubtless be some patients who will

prefer its employment in their case. For these reasons, then, it is a method well worthy of prolonged study, and we shall note with interest its records during the next few years.

The Odontological Collection of the Royal College of Surgeons of England.

By a happy coincidence the Council of the Royal College of Surgeons of England was able, while celebrating on Dec. 2nd the jubilee of the right of the College to grant Licentiateships in Dental Surgery, to open for inspection the most extensive and valuable collection of specimens ever brought together to illustrate the anatomy, evolution, and pathology of the teeth. The coincidence was even happier than most of those who took part in the opening ceremony were aware, for the movement which induced the College to acquire the power to grant dental diplomas also led to the foundation and expansion of the collection now entrusted to the care of the College. That movement was set on foot some 55 years ago by the leading dentists of England, who were dissatisfied with the status and conditions of their profession. They combined to petition the Council of the Royal College of Surgeons to secure their status and to confer a diploma—a petition which was granted in 1859 after four years of consideration and negotiation. Out of the combination thus formed grew the Odontological Society of London, a designation changed to that of Great Britain at a later date. Although drawn together for the domestic legislation of their calling the new society, in the words of its first president, Mr. SAMUEL CARTWRIGHT, F.R.S., had as its main object the "collection and diffusion of knowledge relating to their profession"; and the scientific as well as practical nature of its published Transactions quickly raised it to a prominent position. In the second year of its existence, as a matter of chance rather than of design, the society began to accumulate specimens as a means of perpetuating as well as diffusing knowledge-a practice that was soon recognised to be of great value for the progress of knowledge. In 1872, 16 years after the society was founded, about 850 specimens had accumulated in what had gradually come to be called "the museum," and a printed catalogue of the collection, making 77 pages, was prepared by the curator of that date-Mr. CHARLES S. Tomes—and published for the society by Messrs. WYMAN and Sons. In 1882 a second edition was prepared by Messrs. W. and H. Weiss under the direction of the curator, Mr. S. J. HUTCHINSON. The number of specimens then amounted to 2000. A third edition was prepared by the present honorary curator, Mr. J. F. COLYER; the number of specimens—acquired by purchase in some cases, but mostly as donations from members of the society—then numbered over 4000. Under Mr. COLYER'S care the collection grew rapidly in size and value. The cases alone in which the specimens were shown had cost the society over £1500. The collection by this time represented every branch and form of dental activity; it was a scientific collection in the strict meaning of the word. Many of its specimens were unique and could not be purchased or

acquired to order, and from a monetary point of view it must have cost a large sum.

In 1907, when the Odontological Society became merged in the Royal Society of Medicine as its Odontological Section, many of those most interested in the future of their museum began to realise that the bantling they had nurtured was beginning to assume rather too large a size for the space and finance at their disposal. The collection had reached a point when it became of national importance and deserved a place where it might be consulted by all medical men; so the dentists approached the Council of the Royal College of Surgeons of England through the members of their own council, of which Mr. J. H. MUMMERY was the President. Sir HENRY MORRIS, Bart., was then President of the College, and Mr. HENRY T. BUTLIN, now President, was the chairman of the Museum Committee. All these entered into pourparlers in a public spirit. It was found that in order to secure a suitable room for the exhibition of so large a collection it would be necessary to make considerable structural alterations in the College Museum, involving an outlay of some £600 or £700, and that it would require about £200 a year for maintenance. Negotiations between the Councils of the College and of the Odontological Section were brought to a successful issue in June of the present year, the College accepting the collection as a trust, undertaking to maintain the collection in its entirety and to permit certain privileges of access to those who wish to carry out researches in connexion with To secure -a maintenance of the close the collection. relationship which had existed between the collection and the Odontological Section of the Royal Society of Medicine, the original owners accepted the right to appoint five trustees to inspect the collection from time to time, and also to nominate an honorary curator to assist the conservator of the College Museum in arranging and improving the collection. As soon as negotiations were completed steps were at once taken by the Council of the College to carry out the necessary structural alterations in the Museum and other preparations which have been now carried out most successfully according to plans prepared by Mr. E. C. FRERE, A.R.I.B.A. The collection was removed from the premises of the Royal Society of Medicine in Hanover-square to its new quarters in Lincoln's Inn-fields by the servants of the College—without a single breakage—where it is now installed. The new odontological room, more commodious than the old, has three large windows which open on Portugal-street, and is also well provided with artificial light—an advantage it enjoys over the rest of the College Museum. A rearrangement of the specimens was necessary in order to admit the addition of the large collection of odontological specimens—both anatomical and pathological—from the College Museum. The specimens added from the College Museum, although they form a minor part of the collection, constitute one of the most valuable sections. The present arrangement of the odontological room must be regarded as a provisional one, for it is expected that at least a year will be necessary to classify and catalogue the collection in a permanent form. The wealth of the material which has been gathered to

secure a sound foundation for the progress of odontological knowledge is already very evident. The first case, which is intended to serve as an introduction to the whole, contains the specimens prepared by HUNTER to illustrate his classical work "On the Natural History of the Human Teeth," 1771the teeth he burned to demonstrate the arrangement of enamel, the teeth he transplanted, the teeth at one time stained by madder-now, alas! the colour is gone-to show the manner in which they grew. It is most fit that the collection should have such an introduction, for no man did more than HUNTER to place the practice of the dentist on a scientific foundation. The second case illustrates the anatomy and development of the teeth, many of the specimens being preparations by HUNTER. The third case contains specimens illustrating the anatomy of the jaws and mechanism of mastication. The fourth and fifth cases contain a most extensive series of specimens illustrating the eruption of the teeth, many of them donations from Sir John Tomes and from Samuel Cartwright, F.R.S. The sixth case is devoted to the dentition of the various races of mankind The seventh to the thirteenth cases are set aside to illustrate the comparative anatomy of teeth. The large section given to comparative dental pathology is a complete illustration of the numerous and important contributions made to the Transactions of the Odontological Society during the last 50 years. Every conceivable—some of them almost inconceivable-abnormality in the size, shape, arrangement, eruption, and implantation of the teeth is richly illustrated. Malformations and diseases of the jaws, diseases and tumours of the teeth, have their full representation Amongst the most interesting sections are those devoted to dentures, artificial teeth, and dental instruments. The evolution of the plate, of the artificial tooth, and of the extraction forceps tells a story of rapid development.

We publish this week a letter from Mr. R. CLEMENT LUCAS urging the creation of a research and teaching demonstratorship in connexion with this dental museum "for the modest sum of £10,000." If such a modest sum be forthcoming there can be no doubt that it would be well expended in the scientific tilling of such a rich field as the new dental museum affords. It must be remembered that the collection, though excellent, is not complete, and it is to be hoped that the public spirit which has made it what it is will ensure its ultimate perfection, for it is a national collection brought together by the Odontological Society and maintained by the Royal College of Surgeons for the use of every serious student who desires by study and research to improve the means for securing the health of the teeth. To a very considerable extent that also implies the happiness of a nation.

PROPOSED COTTAGE HOSPITAL FOR ST. AUSTELL (CORNWALL).—A public meeting was recently held at St. Austell, when it was unanimously decided to erect a cottage hospital for the town and district. The late Mrs. Doidge has bequeathed £500 towards the building provided the institution is established by July, 1911, and the chairman remarked that with such a substantial donation it was practically certain that the hospital would be completed by the specified date.

Annotations.

"Ne quid nimis."

THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

A MEETING of the National Committee for Great Britain and Ireland of the International Congress of Medicine was held at the rooms of the Medical Society of London on Thursday, Nov. 25th, Dr. F. W. Pavy, F.R.S., President, in the chair. There were present Sir William S. Church, Bart., Sir Thomas Barlow, Bart., Sir Dyce Duckworth, Bart., Sir John Tweedy, Sir Malcolm Morris, Sir Shirley Murphy, Professor W. Osler, Mr. Butlin (President of the Royal College of Surgeons of England), Dr. D. Ferrier, Deputy Inspector-General J. J. Johnson, R.N., Dr. J. F. Gordon Dill, Dr. W. P. Herringham, Dr. A. E. Garrod, Dr. Donald W. C. Hood, Dr. J. F. Goodhart, Mr. W. H. H. Jessop, Dr. StClair Thomson, Mr. Hunter F. Tod, Mr. L. Eliot Creasy, the honorary secretaries (Dr. Clive Riviere and Mr. D'Arcy Power), and others. Mr. D'Arcy Power read a report on the Sixteenth Inter. national Congress of Medicine, which was held at Budapest at the end of August. The British contingent numbered 94, and the meeting was said to have been very successful and to reflect great credit on the executive committee. The report pointed out that the Congress had decided to appoint a permanent committee consisting of the presidents, the secretaries, and some members of the various national committees. The permanent committee was not to number more than 50 members and there was to be a secretary paid out of the funds of each forthcoming congress. The offices of the permanent committee were to be at The Hague. Dr. Pavy notified to the meeting the acceptance of the invitation of the National Committee for Great Britain and Ireland, with the approval of His Majesty's Government, to hold the Seventeenth International Congress in London in the year 1913. It was thereupon proposed by Sir John Tweedy, seconded by Sir Dyce Duckworth, and carried unanimously, that a general committee be formed to undertake the organisation required for the meeting of the Congress in London. It was further proposed by Sir William Church, seconded by Mr. Butlin, and carried, that the National Committee for Great Britain and Ireland be dissolved and immediately reconstituted as the general committee for this purpose, the general committee having power to add to its numbers. It was decided that the first meeting of the general committee should be held in February next, the officers of the National Committee holding their present positions until new officers were nominated and elected. Professor Osler moved that it be an instruction to the general committee to see that the colonies are adequately represented in all matters connected with the Seventeenth International Congress of Medicine. The meeting ended with a vote of thanks to the Medical Society of London for the use of the meeting room. Mr. D'Arcy Power and Dr. Clive Riviere will be glad to receive the names of those who are interested in the forthcoming Congress as soon as possible.

THE MEDICAL MAN AS SOCIAL REFORMER.

In a paper under the above heading which appeared in the Edinburgh Medical Journal of November Dr. Lachlan Grant advocates some sweeping reforms in medical service generally, with perhaps special attention to public health. He begins by calling attention to the fact that of recent years the medical man has become recognised as "an all-important factor in the life and progress of the people," and goes on to refer to the duty laid upon medical men of

improving the public health and social conditions in general. But he reminds his readers that medical officers of health are neither ubiquitous nor all-powerful and that the private medical practitioner in most cases cannot afford to jeopardise his bread and butter by agitating for the removal of evils for the continuance of which public apathy, private interests, and the fear of raising the rates are responsible. All this has been said before, but it will bear repetition if there is no exaggeration. From this point Dr. Grant is led to his first thesis, that "there should be a reorganisation and a coördination of all medical and public health activities, dealing with all hospitals, dispensaries, factories, workshops, warehouses, mines, railways, ships, hotels, schools, restaurants, and private dwellings." Further, "all hospitals, infirmaries, convalescent homes, and nurses' training schools and institutions should be taken over and kept up by the public authorities." and there should be established "a separate independent governmental department for the administration of public health, with a political chief of the dignity of a Cabinet Minister." This is a programme of destruction and construction more complete than is projected by the reports of the Royal Commission on the Poorlaw, and we are sure that the country is not yet ready for the complete nationalisation of the medical service, however clear it is that some drastic reforms of existing methods are imminent. The establishment of a Minister of Public Health is much to be desired, but until a Government arises which will have the courage to avoid wasting its time upon what a sixteenth century author (Erasmus, if we remember rightly) called "vermiculate disputations," we doubt if such a desirable consummation will be effected. That various social reforms are much needed is a truism obvious to everyone; neither is their need confined to this country alone. The exodus from the country into the towns, the stress of modern industrialism, the decline in the birth-rate, and the ominous fact that the most prolific portions of the body politic are the wastrel and the unskilled worker, are signs of decay which are to be seen in almost every European country. But although the subject is so vast that a remedy cannot be formulated which will at once cure all the evils in evidence, yet that is no reason why those in power should not seek some means for, at all events, a commencement of improvement, and for that commencement such suggestions as can be found in Dr. Grant's paper and elsewhere merit consideration. They should make people think.

AN "ILLUMINATING" SOCIETY.

THE formation of a society which, in the words of Professor Silvanus Thompson, has been founded "to bring together all those who are interested in the problems, practical and theoretical, of the art of directing and adapting light," will be welcomed. The rapid development in methods of illumination during the last few years has made for both the convenience and inconvenience, the comfort and discomfort, of man. The race for a supreme light has been directed to producing intense illumination without regard to the healthy requirements of the eye. The brilliancy of the artificial light has been considerably increased, but little attention has been given to new means of diffusing it. When the source of light is concentrated at a given point the eye shrinks at the glare and dazzle of the rays, whereas if the intensity of such a light could be distributed the result would be pleasing and comfortable. Questions of in-door artificial lighting also are questions of considerable hygienic importance, and yet little has been done to help us in the choice of a light in relation to its effect upon the eyesight. So far we have been at the mercy of the lamp-maker and the fitter, who as

often as not exhibits complete ignorance as to the best situation for a lamp. The subject has long called for investigation, and as the work of inquiry proceeds it will not be surprising if certain disorders are definitely traced to faulty methods of illumination. We wish success to the Illuminating Engineering Society, which held its first meeting at the Royal Society of Arts on Nov. 18th last, and the next meeting of which takes place on Jan. 11th, when a discussion on "Glare, some of its Effects and Causes," will be opened by Mr. J. H. Parsons.

HOOK-WORM DISEASE IN THE SOUTHERN STATES OF AMERICA.

THE announcement made recently that Mr. John D. Rockefeller had given £200,000 to be employed in the effort to extirpate hook-worm disease from the Southern States has drawn attention to the extreme prevalence of the disease in that portion of the United States.1 Few persons on this side of the Atlantic have any conception of how great a scourge the small nematode—ankylostoma duodenale—is in the southern part of North America. It is a somewhat curious fact that the negroes of the Southern States, although it is suspected that they were instrumental in introducing the disease, do not suffer to any marked extent from it. They seem to have acquired immunity. It is the poorer white inhabitants of certain districts of the South who are notorious for their shiftless, lazy habits, who seem to be without energy and without vigour-so much so, indeed, that they are colloquially referred to as "mean white trash "-who are the sufferers. Their unfortunate physical and mental condition is largely ascribable to the effect of ankylostomiasis, or, as the malady is termed in America, uncinariasis. Dr. Charles Wardell Stiles, chief of the Division of Zoology of the Hygienic Laboratory of the United States Public Health and Marine Hospital Service, has stated that in his opinion the inferior mental, physical, and financial condition of these poor whites is an important pathological factor. An American correspondent writes on the subject as follows:-"The extent to which the disease prevails is a matter of some surmise. It has been estimated that 700,000 of the inhabitants of Puerto Rico are carriers of the hook-worm, and that 90 per cent. of the total population of the island are infected. Some observers in South Florida have stated that a like percentage of the population of that state suffer from the same cause, while other American statisticians assert that at the present time there are 2,000,000 southerners. mostly children, afflicted with hook-worm disease." The prevention of the disease is not difficult in theory, but in practice it will undoubtedly prove by no means easy if there is anything like the prevalence indicated. The main measure to be adopted, which if effectively carried out may be sufficient in itself to stamp out the disease, is careful disposal of excreta. It is known that the ova of the parasite although deposited in the human intestine do not develop there, but pass out with fæcal matter and develop in the soil. Therefore if fæcal contamination of the soil be prevented ankylostomiasis should be extirpated. But to carry a campaign of this kind to a successful issue requires not only a very large sum of money, but necessitates on the part of those to whom the work is entrusted the employment of infinite care and perseverance. The habits of shiftlessness and indifference to the laws of health are doubtless thoroughly ingrained in the people of the Southern States of America, and to remove their prejudices and to induce them earnestly to cooperate in measures of sanitary reform will be a task of unusual magnitude. However, the names of the commission now

chosen to conduct this crusade should be a sufficient guarantee that, in any event, the question will be approached with a full knowledge of its difficulties and also of the best means to overcome them. Although not perhaps material to the matter, it is interesting to note that Stiles and Looss now hold that the American species of hook-worm should not be classed with uncinaria and the name of necator Americanus has been suggested. With regard, too, to the causation of the anæmia of ankylostomiasis opinions differ somewhat. As to whether it is produced by blood abstraction, to venom secreted by the head glands of the parasite, or to secondary infection. Dr. L. W. Sambon in 1908, referring to these points,2 was inclined to favour the microbic theory of causation. Stiles, discussing the same points in Osler's "Practice of Medicine" has said: "The constant drain on the system by the sucking of blood can no longer, as formerly, be regarded as the chief cause of the anæmia. Through the wounds bacterial infection may take place; the wall of the bowel may be much thickened and degenerated, so that its functions are interfered with; and lastly, it is quite possible that toxic substances are produced by the parasites which act injuriously upon the patient." The Rockefeller Commission should clear up some of the obscure features in connexion with the disease.

THE INCREASE OF POPULATION IN ENGLAND AND WALES.

THERE is something apparently paradoxical in the statistical fact that, in spite of the marked and steady decline of the birth-rate in England and Wales, the actual number of births continues to increase. The obvious explanation of this fact is, however, that the excess of births over deaths in this country is still causing a steady and rapid increase of population, notwithstanding the decline of the birth-rate. Moreover, the decline in the birth-rate has been accompanied by a marked and steady decline in the death-rate, which has to some extent counterbalanced the effect of the reduced birth-rate upon the increase of population. During the five years 1871-75 the mean annual birth-rate in England and Wales reached its maximum, and was equal to 35.5 per 1000; the mean death-rate during the same period was 22 0 per 1000. Thus the annual natural increase of population during this quinquennium was equal to 13.5 per 1000. During the most recent completed quinquennium, 1901-05, the annual birth-rate had fallen to 28.1 and the death-rate to 16.0 per 1000. Thus the mean annual natural increase of population, which had been equal to 13.5 per 1000 in 1871-75, did not fall below 12.1 per 1000 during the five years 1901-05. While, however, the rate of natural increase of population, notwithstanding the marked decline of the death-rate, showed a distinct decrease during the 30 years referred to, the annual number of registered births continued to increase, owing to the constant additions to the population by excess of births over deaths. During the five years 1871-75, with a birth-rate of 35.5 per 1000, the average annual number of births registered in England and Wales did not exceed 831,735; whereas in the five years 1901-05, although the birth-rate had fallen to 28.1 per 1000, the average annual number of registered births had increased to 938,654. Similarly, notwithstanding the decline during the 30 years of 1.4 per 1000 in the annual rate of natural increase of population, the actual numbers annually added to the population, which averaged 317,185 during the five years 1871-75 had increased to 404,341 during the last completed quinquennium, 1901-05. Thus

while both the birth-rate and the rate of natural increase of population had distinctly and continuously declined during the 30 years, the number of registered births and the amount of natural increase of population continued steadily to increase. It is interesting to note that while the mean-rate of natural increase of population, by excess of births over deaths, was equal to 12·1 per 1000 during the five years 1901-05 in England and Wales, it was during the same period equal to 14·3 in the German Empire, 14·2 in Denmark, 14·1 in Norway, 10·7 in Italy and in Belgium, 10·6 in Sweden, 10·4 in Switzerland, 9·2 in Spain, and only 1·6 per 1000 in France. The population of England and Wales is therefore still increasing, by excess of births over deaths, at a greater rate than that of most of the Continental States.
